1. Executive summary

2nd TW-Biomonitoring cement plant - Cementáreň Turňa nad Bodvou, Slovakia - May 2024

In 2023, the civil organisation Zelený živel o.z. representing environmentally concerned residents of Turnianska kotlina, took the initiative to contact Zero Waste Europe in Belgium and ToxicoWatch (TW) in the Netherlands. The first TW research, started with initial biomonitoring on October 30-31, 2023, in the region of Turňa nad Bodvou, near the cement kiln. This second biomonitoring research, started on May 8-11th 2024, is a follow-up. The TW research aims to assess the deposition of persistent organic pollutants (POPs), such as dioxins (PCDD/F/dl-PCB), Polycyclic Aromatic Hydrocarbons (PAH), PFAS, and Heavy Metals (HM), in the surrounding area of the cement kiln. For this multi-year study (2023-2025), the area around the cement plant Cementáreň Turňa nad Bodvou located in the Košice Region of Slovakia is the central location for biomonitoring research. Reference samples were from the Slovak Karst National Park (NP Slovenský kras), with the guidance of official park rangers. All analysis results were performed by accredited labs in the Netherlands.

From May 8-11, 2024, 63 samples were collected by the TW team, including eggs/eggshells of backyard chicken, wildlife meat of deer, Carp fish (*Cyprinus carpio*) wildlife bird eggshells of Heron (*Ardea*), mosses (*Bryophyta*), pine needles (*Picea abies*), water from natural water stream and wells, sediment from natural water streams and wells, and soil.

Key Findings of the 2nd TW biomonitoring:

1. Exceeding values for dioxins of the EU limit of 3.3.pg BEQ/g/fat (Dr CALUX) and 5.0 TEQ/g fat (GC-MS) were found in the eggs of backyard chickens.
2. The results of dioxins in mosses (*Bryophyta*) and pine needles (*Picea abies*) were highly elevated compared to reference sites.
3. Dioxin patterns (congeners) indicate a source of co-incineration of alternative industrial fuel.
4. Analysis of 14 Heavy Metals (HM) - Silver (Ag), Aluminium (Al), Arsenic (As), Barium (Ba), Cadmium (Cd), Cobalt (Co), Chromium (Cr), Copper (Cu), Mercury (Hg), Manganese (Mn), Nickel (Ni), Lead (Pb), Tin (Sn) and Zinc (Zn) – showed elevated levels of all heavy metals in mosses (*Bryophyta*) compared to the references from the Slovak Karst National Park (NP Slovenský kras), EU-limits and average levels of heavy metals in vegetables.
5. Comparative studies by Danucem Slovensko a.s., (conducted by Ekotoxikologické centrum Bratislava, ECB) and the Košice Regional Government (conducted by Ekolive) confirm the findings of TW regarding increased dioxins in backyard chicken eggs but underestimate the elevated presence of Heavy Metals (HM) in vegetation and soil this research area.
6. The analysis results in sediment at the reference sites in the Slovak Karst National Park > 20 km west of the cement kiln show significantly lower values than the results of fourteen (14) heavy metals in the soil at seven (7) sites within a radius of 3.5 km around the cement plant.
7. A seriously contaminated children's playground in Dvorníky-Včeláre, located just 630 meters north of the cement kiln, was found to contain high levels of lead (Pb) and Arsenic (As).
8. High concentrations of Heavy Metals (HM14) were found in Mosses (*Bryophyta*), near the cement kiln, indicating a serious contamination of the soil in private vegetable gardens.

9. PFAS contamination, with chemical analysis LC-MS/MS on Σ 24 PFAS substances, was found at all backyard chicken egg locations.
10. High values of PFAS with the PFAS CALUX assay were found in Brook Turňa (potok Turňa) water stream and sediment near the cement kiln, compared with the wells of Brook Turňa (potok Turňa) water wells at reference locations in the Slovak Karst National Park, Hrhov, Jablonov and Zádiel.
11. PFOS contamination was detected in the liver of Carp fish (*Cyprinus carpio*) from Lake Hrhov (Hrhovské rybníky), based on chemical PFAS analysis (LC-MS/MS Σ 24).
12. Specific combustion-related PAH congeners (4- and 5-ring), such as Benzo[a]pyrene, were found in mosses (*Bryophyta*) and pine needles (*Picea abies*) in the surrounding area of the cement kiln, notably also in pine needles (*Picea abies*) at one location within the protected area of Slovak Karst National Park.
13. The specific congener patterns of dioxins (PCDD/F/dl-PCB) and polycyclic aromatic hydrocarbons (PAH Σ 16) in the eggs of backyard chickens and vegetation showed elevated levels of combustion-related contamination.

These findings are a clear call for action for the responsible authorities to ensure that people living in the surrounding area of the cement kiln are provided with an environment free from industrial POP emissions. The precautionary principle should be applied as a guideline in this regard.

ToxicoWatch strongly recommends:

1. A structural, yearly biomonitoring research programme on POP emissions, to monitor increases or decreases in POP contamination in the surrounding environment of the cement kiln in Turňa nad Bodvou.
2. The establishment of a Technical Working Group (TWG) involving all parties (independent research, representatives of concerned citizens, regional government, and the cement kiln industry), to work on technical improvements, such as filter systems, and a transparent monitoring system of for flue gas emissions of POPs and dust emissions from mining, production, transport, and waste. This initiative aims to stop the contamination of the area where people live and the surrounding natural environment of the Slovak Karst National Park.

Biomonitoring results highlight the underestimation of emissions of dioxins, PFAS, PAH and heavy metals from the cement industry.

3. Introduction

This second ToxicoWatch (TW) biomonitoring study focuses on the sampling conducted from 8-11, 2024, in the surrounding environment of the cement plant - Cementáreň Turňa nad Bodvou. It is a follow-up to the first published biomonitoring report based on the sampling from October 30-31, 2023.

Thirteen (13) different (bio)matrices were sampled: eggs and eggshells from backyard chickens, eggshells of wildlife birds Heron (*Ardea*), mosses (*Bryophyta*), pine needles (*Picea abies*), meat of a domestic cow, wildlife meat of deer and Carp fish (*Cyprinus carpio*), soil, sediment, water from natural water streams and sheep wool. In total, sixty-three (63) samples were collected and analysed for 1 to 4 different kinds of POPs, including dioxins, PFAS, PAH, and 14 heavy metals (HM): Silver (Ag), Aluminium (Al), Arsenic (As), Barium (Ba), Cadmium (Cd), Cobalt (Co), Chromium (Cr), Copper (Cu), Mercury (Hg), Manganese (Mn), Nickel (Ni), Lead (Pb), Tin (Sn), and Zinc (Zn). (Bio)assays were used to monitor non-targeted dioxins (by DR CALUX), PFAS (by PFAS CALUX), and PAH (by PAH CALUX). Besides these (bio)assays, chemical analyses were performed on dioxins (PCDD/F/dl-PCB with GC-MS), PFAS (LC-MS/MS), and PAH (GC-MS/MS).

Ecologically significant areas adjacent to the second TW sampling site include the Protected Bird Area Slovak Karst (SKCHVÚ 027) and the National Nature Reserve - Zádiel Gorge (Zádielska dolina), part of the Slovak Karst National Park.

To interpret the analytical results for persistent organic pollutants (POPs), such as dioxins, PFAS, PAHs and heavy metals that were detected in the May 2024 collected samples, the geological environments of the hills surrounding the cement kiln must be considered, especially concerning wind fumigation and the subsequent deposition of these substances of very high concern (SVHC).

Figure 2: Area of TW biomonitoring research, the surrounding environment of the cement kiln near the villages of Dvorníky-Včeláre, with the Slovak Karst National Park in the distance, May 11, 2024.

4. Cement kiln industry

4.1. General production

The cement industry, in general, has two distinct faces. On the one hand, it forms the backbone of society and is closely linked to a country's economic development. It provides jobs and serves as a significant financial source of financial income for many countries. Concrete and cement are therefore essential, with current global production reaching as much as 1 tonne per person per year.¹

The ambitions of the cement industry are notably high, as reflected in numerous industry publications.² However, it is striking that hardly a word is devoted to the emissions of substances of very high concern (SVHC). Is the cement industry ready to eliminate toxic emissions? Investigating environmental releases of persistent organic pollutants (POPs) would be a worthwhile initiative.

Currently, the heavily promoted 'green card' of reducing CO₂ emissions - since cement kilns are significant contributors to CO₂ -, seems to overshadow the critical need to address the elimination of hazardous toxic emissions, like dioxins, PFAS, PAH, and heavy metals. These pollutants, emitted by the cement industry, take a heavy toll on the surrounding environment.

The health of the population living near these facilities is under constant pressure due to inadequate monitoring of dioxins, PFAS, PAHs, and heavy metals. Substances like dioxins, which are extremely toxic even at very low concentrations, remain minimally monitored. Yet, due to their persistence, bioaccumulation, and toxicity, they are carcinogenic, mutagenic, reprotoxic, and neurotoxic – posing significant risks to human health and the environment.

Figure 3: PBT – Persistent-Bioaccumulation-Toxic features of POPs

4.2. Cement plant - Cementáreň Turňa nad Bodvou

It is to be welcomed that both Danucem Slovensko a.s and the Košice Regional Government have started biomonitoring studies in 2024 via Ekotoxikologické centrum Bratislava (ECB) and Ekolive, respectively. Biomonitoring on POPs in the environment should be conducted structurally by independent parties with no financial interests or political ties to the cement kiln industry. Monitoring the environment on behalf of public communities provides insight into the level of POP contamination over time, which could lead to technical improvements in the cement kiln production line to eliminate toxic contamination in the environment.

The upcoming permit to increase capacity and switch to alternative fuels, such as used car tyres and waste oil, could exacerbate the POP contamination problem in the environment. Many researchers warn about the negative impact of the combustion of alternative fuels, such as used car tyres, plastic waste, and PCB oils. If a permit is granted based on a monitor commitment that only covers 0.1% of production time for highly toxic substances like dioxins, this is not a genuine effort to reduce hazardous emissions. Not to mention the extremely short time frame for monitoring the conglomeration of heavy metals. In addition to the absence in the mandatory measurements of Aluminium (Al), Barium (Ba), Mercury (Hg), Cadmium (Cd), Zinc (Zn), Tin (Sn), and Silver (Ag), hardly any heavy metals are monitored in the end products.³ PFAS also does not seem to be controlled at all, even though these substances are abundantly present in the waste stream and are detected near the cement kiln (see Chapter 7).

Several studies have highlighted complaints from residents about air pollution when cement kiln plants are located nearby. People living close to the plant often experience confusion and public irritation due to the thick layer of dust that collects on house roofs, in (vegetable) gardens, and on parked vehicles. Unfortunately, many of these residents are still unaware of the potential risks of cement dust in their vicinity, leaving them constantly exposed to a variety of toxic pollutants. Cement production is inextricably linked to air and environmental pollution. Switching to alternative fuels can cause more environmental damage than fossil fuels, despite the green labelling. This is especially true for the burning of used car tyres, plastics, and waste oils.⁴ Combustion of used tyres produces atmospheric pollutants such as dioxins, dibenzofurans, NO_x, SO_x, and heavy metals such as Ti, Al, Pb, Ni, Mn, Fe, Cr, and Zn.⁵ However, data from Danucem Slovensko a.s. cement plant - Cementáreň Turňa nad Bodvou reported 0.0 kg of use of end-of-life tyres use (Code 16 01 03, European Waste Catalogue) for 2023.⁶ This data conflicts with the information TW received from concerned residents and contrasts with the upcoming permit to incinerate used car tyres as an alternative fuel. Most significantly, the results of this study indicate serious contamination of dioxins, PAH, PFAS and heavy metals in the environment of Turňa nad Bodvou, which can also be explained by the burning of alternative fuels.

4.2. Cement kiln Dust emissions

There is a lack of thorough biomonitoring research on the deposition of hazardous substances such as dioxins and heavy metals in the environment surrounding cement kilns, open mining lime pits, and co-incinerator plants. The mining industry has significantly contributed to national economic development by supplying raw materials, offering employment opportunities, and spurring regional economic growth. However, it has caused varying degrees of ecological damage in the vicinity of mining sites, including vegetation destruction, soil erosion, atmospheric and water pollution, and waste accumulation, all of which threaten the sustainability of both the economy and the environment.⁷ The main environmental issues associated with lime production are air pollution and energy use. The lime-burning process is the primary source of emissions and the principal energy consumer. Secondary processes such as lime slaking and grinding can also contribute to hazardous dust pollution, while subsidiary operations (namely crushing, screening, conveying, storage, discharge and shipment) are minor in terms of both dust emissions and energy usage.⁸

Three types of dust emissions must be considered: first, limestone dust (from the production of raw limestone material extracted from the mountains); second, dust from the cement kiln industry during production; and third, cement dust emissions from manufacturing of products, storage, bagging, and shipment.

Figure 5: Infographic of pathways of cement kiln dust

Lime is produced by burning calcium and/or magnesium carbonates at temperatures between 900 and 1200/1400°C. The chemical reaction of calcium carbonate thermal decomposition is often referred to as 'calcination' and can be expressed as follows:

Calcination in the cement kiln production process accounts for 44% of CO₂ emissions, which is a substantial contribution from this industry sector. Dust emissions of persistent organic pollutants (POPs) should not be overshadowed by efforts to reduce CO₂ emissions (since the cement kiln industry is a large contributor to CO₂) by utilising high-risk alternative fuels (such as contaminated plastic, rubber, tyres, PCB oils etc.) under a 'green' label promotion. In addition, more biomonitoring should be applied to the mining of limestone and the dust emissions during production, transport, use of products (cement), and disposal of end-of-life products (cement).

5. Sampling & Analyse methods

This second biomonitoring report should be read as a follow-up to the first biomonitoring report, which was published and presented at the local village hall in the village of Dvorníky-Včeláre on May 7, 2024.

In this second biomonitoring report, based of TW sampling from May 8-11, 2024, the focus is on eggs from backyard chickens owned by private chicken coop owners, mosses (*Bryophyta*), pine needles (*Picea abies*), soil, sediment, water, meat from a domestic cow, and wildlife meat from deer and Carp fish (*Cyprinus carpio*), as well as eggshells of backyard chickens and wildlife birds Heron (*Ardea*).

The persistent organic pollutants (POPs) targeted by lab analysis are dioxins, PFAS, PAH, and 14 heavy metals: Silver (Ag), Aluminium (Al), Arsenic (As), Barium (Ba), Cadmium (Cd), Cobalt (Co), Chromium (Cr), Copper (Cu), Mercury (Hg), Manganese (Mn), Nickel (Ni), Lead (Pb), Tin (Sn), and Zinc (Zn). By applying bioassays (DR CALUX), a much broader spectrum of dioxin toxicity is detected than with the very limited 29 chlorinated dioxins identified by chemical GC-MS analysis. PFAS and PAH are also monitored in this research using screening assays like PFAS CALUX and PAH CALUX, for the same reason as for dioxins, allowing a much broader scan of their toxicity, beyond the limited chemical analysis of 24 PFAS substances and 16 PAH compounds.

Ecologically significant areas are adjacent to the cement kiln, including the Protected Bird Area Slovak Karst (SKCHVÚ 027) and National Nature Reserve - Zádiel Gorge (Zádielska dolina), which forms part of the Slovak Karst National Park. The sample objectives and locations are summarised in the sample overview map below. An overview of locations, analysis methods and results for each (bio)matrix can be found in the attached Annex 1.

A total of 63 samples were collected by the TW team from May 8-11, 2024. All analysis results were performed by accredited labs in the Netherlands: BioDetection Systems (BDS), Amsterdam and Normec, Groen Agro Control in Delfgauw. The official lab analysis reports of this 2nd research are attached in Annex 2.

Figure 6: TW 2nd sampling overview map, May 8-11th 2024

5.1. Soil

From May 8-11 of this year, TW took fourteen (14) soil samples from nine (9) locations in all wind directions within a 3,5 km radius surrounding the cement plant - Cementáreň Turňa nad Bodvou. Soil samples were taken from private property and a public children's playground and open-air sports facility located 630 meters north of the cement kiln. See Annex 1: Samples & Analysis Overview

Soil samples of more than 100 grams were taken from the top layer of the soil (< 5 cm) and collected in plastic LDPE lab bags. The collected soil samples were stored dry, cool and dark until lab analysis.

Figure 7: Soil sample locations & analysis, May 8-11th 2024

5.2. Water

Water samples were collected from six (6) natural water streams. Two samples from the Slovak Karst National Park were taken as reference samples. Locations one (1) and two (2) were collected with the permission and guidance of official park rangers of the Slovak Karst National Park, located 25-30 km west of the cement plant. Location five (5) is from the Hrhov natural water well stream, 7 km away, and can therefore be considered as a reference sample. Location four (4) is from the natural water stream running through the centre of the village of Zádiel. At Location Six (6), water was sampled from a stream passing by the Jablonov Gas plant, located 12 km west of the cement kiln. Location one (1), Brook Turňa (potok Turňa), is situated 100 m southeast of the cement kiln. The natural brook is used for both water intake and discharge for production processes by the cement plant.

For each location, TW collected 2x 500 ml water samples, which were directly stored in plastic HDPE lab containers. The samples were stored dry, cool and in the dark until lab analysis.

At three (3) locations, water samples were analysed for PFAS using a chemical analysis method (LC-MS/MS) for 24 PFAS substances. At these same three (3) locations, a bioassay (PFAS CALUX) was performed to measure a broader range of PFAS toxicity. Additionally, at three (3) water sample locations, heavy metal analyses (Ag, Al, As, Ba, Cd, Co, Cr, Cu, Hg, Mn, Ni, Pb, Sn and Zn) were performed.

Figure 8: Water sample locations & analysis, May 8-11th 2024

5.3. Sediment

Sediment samples were taken at five (5) locations. At each location, 2x 500 ml plastic HDPE lab containers were filled with sediment sample material. Using a lab spoon, the top sediment layer (< 5 cm) was taken from the water streams. All the collected sediment samples were stored dry, cool and in the dark until lab analysis.

The sediment samples were analysed using four different methods: 2 samples for dioxins (PCDD/F/dl-PCBs) with the innovative bioassay DR CALUX, 3 samples for 14 heavy metals (Ag, Al, As, Ba, Cd, Co, Cr, Cu, Hg, Mn, Ni, Pb, Sn and Zn), 2 samples for PFAS using the bioassay PFAS CALUX, and 3 samples for PFAS with chemical analysis (LC-MS/MS) for 24 PFAS substances.

Figure 9: Sediment sample locations & analysis, May 8-11th 2024

5.4. Vegetation

There is a fundamental lack of thorough biomonitoring research on vegetation regarding the deposition of substances of very high concern (SVHC), such as dioxins, PFAS, PAH, and heavy metals, in the environment of the cement kiln industry. TW has monitored fourteen (14) heavy metals, dioxins, and PAH in mosses (*Bryophyta*), pine needles (*Picea abies*), as well as in fruit, and correlated the analysis results with the EU limits for feed (animal and pet food) and food.

5.4.1. Pine needles (*Picea abies*)

At eight (8) locations, pine needles were collected from pine trees (*Picea abies*) at private locations in all wind directions within a 3,5 km radius of the cement kiln. These locations are three (3), four (4), six (6), seven (7), and eight (8). The reference location in the Slovak Karst National Park included two (2) pine needle samples (1A and 1B) at 25 km to the west. The reference samples were taken at this location with the permission and guidance of the official rangers of the Slovak Karst National Park (SKNP).

At each location, the pine needles were taken from different branches of the pine tree (*Picea abies*) at a height of 1.50-2 meters in various wind directions. The sample material (> 100 grams) was stored in plastic LDPE lab bags and kept dry, cool and in the dark until lab analysis. The pine needles were analysed for different substances using three analytical methods: six (6) samples were analysed for dioxins (PCDD/F/dl-PCBs) with the innovative bioassay DR CALUX, all eight (8) samples were analysed for polycyclic aromatic hydrocarbons (PAH) using chemical analysis PAH/HP-LC-FLD/ GC-MS/MS) on 16 PAH substances; and all eight pine needle samples were analysed for 14 Heavy Metals (Ag, Al, As, Ba, Cd, Co, Cr, Cu, Hg, Mn, Ni, Pb, Sn, and Zn).

Figure 10: Pine needles (*Picea abies*) sample locations & analysis, May 8-11th 2024

5.4.2. Mosses (*Bryophyta*)

In the second biomonitoring, moss samples from seven (7) locations (4-10), both private and public, within the 3,5 km radius surrounding the cement kiln were collected. The mosses were collected from stone, wood, or metal roofs of sheds, as well as from soil/ground. For reference, moss samples were collected from three (3) locations (1-3) in the Slovak Karst National Park, from natural decaying tree trunks and forest floors. This was done with the permission and guidance of the official park rangers, at 25-30 km to the west.

The collected moss samples (> 100 grams) were stored in plastic LDPE lab bags, and kept dry, cool and in the dark until lab analysis. The moss samples were analysed for different substances using four analytical methods: 8 samples were analysed for dioxins (PCDD/F/dl-PCBs) using the innovative bioassay DR CALUX.

Figure 11: Mosses (*Bryophyta*) sample locations & analysis, May 8-11th 2024

All ten (10) moss samples underwent heavy metal analysis for 14 elements (Ag, Al, As, Ba, Cd, Co, Cr, Cu, Hg, Mn, Ni, Pb, Sn and Zn). For polycyclic aromatic hydrocarbons (PAH), six (6) samples were analysed using the chemical analysis method PAH/HP-LC-FLD/ GC-MS/MS for PAH Σ 16 substances, and 7 samples were analysed for PFAS using chemical analysis (LC-MS/MS) for PFAS Σ 24 substances.

TW has monitored heavy metals in moss, pine needles, and fruit. The findings are compared with the EU limits of feed (animal and pet food) and food.⁹ When the limits set for leafy vegetables are applied to the mosses (Bryophyta) as bioindicators, excess levels can be observed for most, if not all metals.

Figure 12: Mosses (Bryophyta) Reference sample locations & analysis, May-11th 2024

⁹ <https://eur-lex.europa.eu/legal-content/EN/TXT/PDF/?uri=CELEX:32023R0915>

5.5. Eggs/eggshells of backyard chicken

In this second biomonitoring study, eggs from backyard chickens were again sampled at the same locations as in the October 30-31, 2023, sampling. In addition to collecting eggs from backyard chickens, chicken feed was sampled at all seven (7) locations for additional analysis of possible confounding substances.

At each egg location, TW collected 9-10 fresh chicken eggs, mixed the egg content (egg white and egg yolk), and stored them in 500 ml plastic HDPE lab containers, kept dry, cool and in the dark until lab analysis.

From May 8-11 of this year, dioxin analysis was performed at seven (7) egg locations using the bioassay DR CALUX. The results exceeding DR CALUX EU limit (1.7 for PCDD/F and 5.0 for the sum of dioxins PCDD/F/dl-PCBs) were additionally analysed by a chemical analysis (GC-MS) for 29 chlorinated dioxins, as required by EU regulation. At five (5) locations, eggshells were analysed for 14 heavy metals (Ag, Al, As, Ba, Cd, Co, Cr, Cu, Hg, Mn, Ni, Pb, Sn, and Zn). This analysis was also performed on eggshells from Herons (*Ardea*) taken from the reference location near Lake Hrhov (Hrhovské rybníky),, with permission and guidance from the official Slovak Karst National Park rangers. At six (6) egg locations of backyard chickens, eggs were analysed for PFAS using the chemical (LC-MS/MS) method for 24 PFAS substances.

5.6. Eggshells of wildlife bird Heron (*Ardea*)

At five (5) locations, eggshells were analysed for 14 heavy metals (Ag, Al, As, Ba, Cd, Co, Cr, Cu, Hg, Mn, Ni, Pb, Sn, and Zn). This analysis was also performed on eggshells from Herons (*Ardea*) taken from the reference location near near Lake Hrhov (Hrhovské rybníky),, with permission and guidance of the official rangers of the Slovak Karst National Park.

Figure 14: Eggshells of wildlife bird Heron (*Ardea*) sample location and analysis, May 8-11th, 2024

5.7. Meat of wildlife deer, Carp fish (*Cyprinus carpio*) and domestic cow

In this second biomonitoring research (May 2024), TW was provided with meat from a young deer (<1 year) by a local farmer. The deer had been living nearby forests of his village, Včeláre. Additionally, meat from the farmer's domestic young calf was provided for analysis on dioxins (PCDD/F/dl-PCB) during the sampling week in May. Both fresh pieces of meat (each 350-500 grams) were handed over in a plastic bag, in a deep-frozen state, as they had been stored for human consumption. The meat was delivered to the lab in this way for analysis.

At the same location where TW collected the wildlife Heron (*Ardea*) eggshells, near **Lake Hrhov (Hrhovské rybníky)**, wild carp fish (*Cyprinus carpio*) was caught for human consumption. A portion of this fresh fish meat (350-500 grams) and the liver were given to TW for analyses on dioxins (PCDD/F/dl-PCB) using the bioassay DR CALUX and for PFAS analysis using the chemical analysis PFAS LC-MS/MS on 24 PFAS substances. The fresh meat was directly stored in a deep freezer in an LDPE lab bag until analyses. The fisherman later mentioned that this fish had been in the freshwater basin near **Lake Hrhov (Hrhovské rybníky)** for only a few weeks after being brought there from another lake.

Figure 15: Meat of wildlife deer, Carp fish (*Cyprinus carpio*), domestic cow location samples & analysis May 8-11, 2024

5.8. Wool of domestic sheep

During the first biomonitoring sampling visit in the region surrounding the cement plant - Cementáreň Turňa nad Bodvou in October 2023, TW collected sheep wool samples from local sheep in the village Včeláre. TW cut the wool directly from the sheep and collected two plastic LDPE lab bags (each > 50 grams) for analysis on dioxins (PCDD/F/dl-PCB) using the bioassay DR CALUX, and polycyclic aromatic hydrocarbons (PAH) using the bioassay PAH CALUX. The sheep wool collection procedure was repeated on the same sheep in Včeláre, although the sheep were now located on the other side of the village, where the sheep shed is also located. In Hostovce. TW was able to sample wool from a small group of sheep. The sheep wool collected in 2024 has not yet been analysed for dioxins and PAH. The results will be implemented in the 3rd biomonitoring report in 2025.

Figure 16: Wool of domestic sheep sample locations and analysis, May 8-11th, 2024

6. Analysis methods

In this second TW Biomonitoring research, DR CALUX and GC-MS were used for dioxin analysis. Polycyclic Aromatic Hydrocarbons (PAH) were analysed by chemical analysis of Σ 16 PAH substances. PFAS were analysed using the PFAS CALUX assay and chemical analysis LC_MS/MS for Σ 24 PFAS substances. Heavy metals (HM) were analysed for 14 elements, with results expressed in mg/kg dry matter (dm, or ds for dry substance). The graph of heavy metals also uses the expression in wet weight, recalculated from the dry matter results.

TW uses a colour-indicative scale to provide better visualisation of the results. The values in these TW colour indicative scales are 2x, 3x, etc. the EU-limits (for chicken eggs, feed, drinking water), or are compared with the background level or occurrence values in vegetables. For the 14 heavy metals, the indicative grey colours are based on 2x, 3x, 4x and 5x the lowest value of the TW results for each specific heavy metal.

Figure 17: TW Biomonitoring lab analysis methods

6.1. Dioxin analysis

The analysis of dioxins (PCDD/F/dl-PCB) starts with the screening bioassay method DR CALUX. This method measures a broader range of dioxin activity compared to the limited chemical analysis (GC-MS), which tests only 29 chlorinated dioxin compounds (see figures below). The chemical GS-MS analysis provides more data on the specific congener patterns of the chlorinated dioxins, which helps to determine the source of the dioxin contamination. See the figures below for EU limits for the bioassay DR CALUX and chemical GC-MS analysis.

Figure 19: Dioxin 29 congeners of chemical analysis (GC-MS) analyses for chicken eggs

Figure 18: Dioxins by bioassay DR CALUX vs chemical (GC-MS)

6.2. Polycyclic Aromatic Hydrocarbons (PAH)

In various national and EU regulations regarding PAHs, the summation of concentrations of 4 or 10 PAH substances is typically adopted. The table below shows the different relative toxicity values, expressed as relative potency (REP) factors. For example, Benzo[b]fluoranthene, the most toxic PAH, is 10,000 times more toxic than anthracene. This demonstrates that simply adding up the concentrations of PAH congeners is insufficient to show the actual toxic load. The regulations need to be updated.

An additional problem, which also affects other highly hazardous substances, is the extremely limited analytical capabilities. Out of the approximately 400 different PAH substances 700, only 16 can be analysed using the chemical analysis method GC-MS/MS, while brominated, chlorinated or other substituted PAHs are not examined.

Nr of rings	PAH	REP
2	Naphthalene*	0*
3	Acenaphthylene	0,0001
3	Acenaphthene	0,0001
3	Fluoren	0,0001
3	Phenanthrene	0,0001
3	Anthracene	0,0001
4	Fluoranthene	0,0001
4	Pyren	0,0001
4	Benzo[a]anthracene	0,3
4	Chrysene	0,8
5	Benzo[b]fluoranthene	5
5	Benzo[a]pyrene	1
5	Benzo[k]fluoranthene	3,7
6	Dibenz[a,h]anthracene	1,3

PAH Σ 4

In the figure below, the 16 different PAH substances are shown and ordered by the number of benzene rings in their PAH molecular structure.

Figure 20: Polycyclic aromatic hydrocarbons (PAH), 16 different congeners

6.3. PFAS

PFAS are widely used in industrial applications and consumer products because of their physical/chemical characteristics such as low grade of degradation, surfactant properties, and thermic flame resistance. Chemical target analyses (LC/MS) accurately quantify individual compounds; however, it may underestimate the total PFAS presence. Many PFAS are possible thyroid hormone (TH) system-disrupting compounds because they can -amongst others- inhibit the TH thyroxine (T4) from binding to its transport protein transthyretin (TTR). An alternative approach to chemical analysis of limited target PFAS substances is to monitor the total contribution of PFAS in the environment by applying the effect-based PFAS reporter gene bioassay.

The Chemically Activated LUCiferase gene eXpression (CALUX) method is a bioassay technique to detect organic compounds like PFAS based on their ability to induce or inhibit the expression of specific reporter genes. The PFAS-CALUX is based on thyroid hormone transport disruption potential, revealing the presence of unknown PFAS beyond the targeted ones. Effect-based PFAS bioassay data correlate well with LC/MS-derived converted data showing that in vitro toxicity analysis of total PFAS content in water samples using the PFAS reporter gene bioassay is a promising and suitable strategy to cover complex mixtures of PFAS and to assess PFAS in water and the environment in general.^{10, 11, 12}

6.4. Heavy Metals (HM)

In TW Biomonitoring research, analysis was performed on 14 elements heavy metals: Silver (Ag), Aluminium (Al), Arsenic (As), Barium (Ba), Cadmium (Cd), Cobalt (Co), Chromium (Cr), Copper (Cu), Mercury (Hg), Manganese (Mn), Nickel (Ni), Lead (Pb), Tin (Sn) and Zinc (Zn). In some cases the lab could analyse 6, 12 or 13 of these elements in specific matrices.

7. Analysis Results of 2nd TW Biomonitoring, May 8-11th 2024

7.1. Results in Soil

The following results have not been received yet: 3 results on dioxins (PCDD/F/dl-PCB) by bioassay DR CALUX, 3x results on polycyclic aromatic hydrocarbons (PAH) by bioassay PAH CALUX, 1x PFAS analysis with the PFAS CALUX assay, and 5 results on heavy metals (14 elements).

7.1.1. Heavy metals (HM) in Soil in general

Heavy metals are ubiquitous in the environment due to both natural processes and human activities, and they pose a significant threat to ecosystems and human health. Sources of heavy metals emissions include mining, (including open lime mining), industrial production (such as foundries, smelters, oil refineries, petrochemical plants, pesticide production, and chemical industry), untreated sewage sludge, and diffuse sources such as metal pipes, traffic, and combustion products from waste incineration and cement kilns.^{13,14} Although several metals are essential for metabolic processes, there is a critical concentration at which toxic effects occur.

¹³ Ogunbileje, J. O. et al. (2013). Lead, mercury, cadmium, chromium, nickel, copper, zinc, calcium, iron, manganese and chromium (VI) levels in Nigeria and United States of America cement dust. *Chemosphere*, 90(11), 2743–2749. doi:10.1016/j.chemosphere.2012.11.058

¹⁴ <https://www.unep-org>.

The research conducted by TW is aimed at protecting the environment, animals, and people, and applies stricter standards than those set by the (Regional) Government of Slovakia (see table). This implies that the standards applied by the Slovak government for soil may pose serious risks to the physical and mental health of the human population, especially children. For instance, in the case of lead (Pb), it means that a child can experience serious cognitive/ learning problems by playing on a playground where lead (Pb) concentrations in the soil have been found, as indicated by the results shown in TW's 2nd biomonitoring study at Dv-04/playground.

The applicable limits for heavy metals in this report by TW are related to levels at which the least damage to humans and nature is expected. For soil, a certain exposure to children is assumed when they play on contaminated soil and, for example, unintentionally ingest soil particles while eating. The RIVM calculations assume 100 mg of soil per day. Additionally, exposure for people working in vegetable gardens should be considered. Consuming products from the vegetable garden, as well as eggs from your backyard chickens, is discussed in the vegetation chapter. The limits for heavy metals in Slovak are shown in the table below.

Emissions of heavy metals from industrial establishments are one of the major sources of environmental pollution. Heavy metals like lead (Pb) and mercury (Hg) in contaminated soils can be transported by water, wind, and other human activities, resulting in health impacts and environmental effects. Cement industries have been reported as a major source of heavy metal emission into the environment, with several studies showing higher concentrations of heavy metals around cement kiln industries.¹⁵

TW performs biomonitoring of hazardous substances of very high concern (SVHC), such as dioxins and heavy metals in the surrounding environment of the combustion-related industries. The limits for heavy metals in this report are related to safe levels of vegetable consumption from private vegetable gardens and safe food limits for eggs from backyard chickens. The differences between the Netherlands/EU and Slovakia are shown in the table below.

Limit levels soil					
		Safe level NL/EU	NL		SK
		vegetable garden/children playground	Industry	Intervention	Ekolive
As	Arsenic	20	76	76	65
Ba	Barium	22 (190)	920	920	900
Cd	Cadmium	0.6	4.3	13	10
Cr	Chromium	55	180	180	450
Co	Cobalt	15	190	190	180
Cu	Copper	40	190	190	500
Pb	Lead	50	530	530	250
Hg	Mercury	0.15	4.8	36	2.5
Ni	Nickel	35	100	100	180
Sn	Tin	6.5	900	900	
Zn	Zinc	140	720	720	1500

¹⁵ Ogunbileje, J. O. et al. (2013). Lead, mercury, cadmium, chromium, nickel, copper, zinc, calcium, iron, manganese and chromium (VI) levels in Nigeria and United States of America cement dust. *Chemosphere*, 90(11), 2743–2749. doi:10.1016/j.chemosphere.2012.11.058

7.1.1.1. Lead (Pb) in Soil

A level of lead (Pb) of 110 mg/kg ds was found at location 4, in the soil of the playground of Dvorníky, 630 m north of the cement plant. The European Food & Safety Authority (EFSA) and the Dutch health services (Rijksinstituut voor Volksgezondheid en Milieu, RIVM) have warned of a decline in children's IQ if lead (Pb) levels are found in soil above the background levels. Exposure to food alone can lead to an increase of lead (Pb) in blood lead levels, EFSA is considered a cause for concern and is associated with an IQ loss of 1 point. A loss of 1 IQ point is significant, affects socio-economic status and labour productivity.¹⁶ Children are mainly exposed to soil lead (Pb) through the ingestion of soil particles.

According to EFSA model calculations, at a soil content of 100 mg/kg lead (Pb), a comparable amount of lead (Pb) (0.53 µg/kg body weight per day) will be ingested via the diet through the ingestion of soil particles during children's activities on the playground.¹⁷

Children are mainly exposed to soil lead (Pb) through the ingestion of soil particles. In the case of vegetable gardens, there is also exposure through the consumption of crops grown on contaminated soil.

Figure 22: Heavy metal, Lead (Pb) in soil, location Dv-04, 2024

For children's playgrounds (both formal and informal), and in (private) gardens, measures should mainly

¹⁶ <https://efsa.onlinelibrary.wiley.com/doi/abs/10.2903/j.efsa.2010.1570>

¹⁷ Otte P.F. (2015). *Diffuse loodverontreiniging in de bodem, Advies voor een gemeenschappelijk beleidskader RIVM Rapport 2015-0204*

focus on reducing the ingestion of soil particles. In addition, the cultivation of consumer crops should be discouraged or adapted (e.g. grown only in containers) to ensure that exposure through the consumption of the cultivated crops is reduced to an acceptable level.¹⁸

For interpretation, EFSA has found a relationship between blood lead levels and neurotoxic effects (such as the loss of IQ points). The calculated relationship is an average value. The effect for an individual child may vary due to differences in factors such as behaviour (exposure), kinetics and sensitivity to lead.

7.1.1.2. Arsenic (As) in Soil

Besides the finding of high levels of lead (Pb) at the playground in Dvorníky, elevated levels of Silver (Ag), Barium (Ba) and Arsenic (As) were found. Arsenic is one of the oldest historical agents of targeted poisoning. The heavy metal arsenic (As) was found at a level of 48 mg/kg ds, which exceeds the Dutch safety limit for Arsenic in soil.¹⁹

Once arsenic is in the environment, it cannot be broken down, so the amounts added can spread globally and harm the health of people and animals. Plants absorb arsenic quite readily, so high concentrations can be present in food. In addition, arsenic is bioaccumulative, which is one reason birds die if they eat fish already containing significant amounts of arsenic.

Figure 23: Heavy metal Arsenic (As) in soil, Location Dv-04, 2024

The graph below shows Arsenic (As) levels in soil across different European countries, with samples

¹⁸ Otte P.F. et al (2015). Diffuse loodverontreiniging in de bodem, Advies voor een gemeenschappelijk beleidskader, RIVM Rapport 2015-0204

from locations in the surrounding area (< 1-3 km) of a waste incineration plant, except for the asterisk-marked locations, where no incinerator is present in the environment.

Figure 24: TW data (Arsenic (As) in Soil in Europe 2007-2024

7.1.1.3. Results Heavy Metals (HM 14) in Soil

The graphs below show the results for each of the 14 specific heavy metal elements in ten (10) locations. To interpret these results TW made a TW colour indicative scale based on the lowest result value of each specific heavy metal. The up-grey colouring is based on 2x, 3x, 4x and 5x of this lowest value. For some metals, the Slovak soil limits for a specific heavy metal are implemented at the bottom of the table in Figure 26.

In the map of this figure, the soil sample locations are marked with a red and/or black triangle concerning the high value of the results at these locations according to TW indicative colour scale for the results.

In this table for reference, Sediment from locations of the Slovak Karst National Park (HRH-01 and KARS-BR) are implemented. The results for the fourteen (14) heavy metals in the reference locations show lower values than the results of heavy metals in the seven (7) locations within a short distance of 3,5 km from the cement kiln.

				Soil (+ Sediment as REFERENCE) and Road material, May 8-11, 2024 : mg/kg (ds)														
Lab date	Lab Nr	TW-REF-NR	Loc.	1	2	3	4	5	6	7	8	9	10	11	12	13	14

Figure 27: Results heavy metals Hg, Mn, Ni, Pb, Sn, Zn in soil, May 8-11th, 2024

7.1.2. PFAS in Soil

Results will be expected in December and will be included in the third biomonitoring report.

7.1.3. PAH in Soil

Results will be expected in December and will be included in the third biomonitoring report.

7.1.4. Dioxins in Soil

Heavy metals, dioxins, and furans with high migration capacity are generated during the incineration process and can cause long-term harm to the environment and human health. This secondary pollution has attracted widespread attention, and as a result, monitoring and controlling hazardous emissions has become an important part of the waste incineration system. TW performs biomonitoring of hazardous substances of very high concern (SVHC), such as dioxins and heavy metals in the surrounding environment of the combustion-related industry.

Results will be expected in December and will be included in the third biomonitoring report.

7.2. Results in Water streams

All six (6) water samples from natural water streams, as shown on the map below, were analysed for PFAS: 3 samples using a chemical analysis (LC-MS/MS) and four water samples using a screening assay PFAS CALUX. The water stream Brook Turňa (Turniansky potok) was sampled at four locations (1, 2, 3, and 6). Sample point 1 of the Brook Turňa, is near the cement plant - Cementáreň Turňa nad Bodvou. Samples 2 and 3 are at the beginning of the well in the Slovak Karst National Park. The analyses were performed chemically with LC-MS/MS and with the bioassay of the PFAS CALUX.

Heavy metal analyses will be performed on three waste samples, with results expected by the end of November or December.

Figure 28: Results heavy metals Hg, Mn, Ni, Pb, Sn, Zn in soil, May 8-11th, 2024

7.2.1. PFAS in natural water streams

Per- and poly-fluoroalkyl substances (PFAS) are pollutants found everywhere in the environment and are known to contaminate drinking water and food sources. Recent research shows that despite high temperatures, PFAS and other fluorinated substances may form and/or persist during incineration, risking release into the environment through air emissions and incinerator residues. Spoilage of technical treatments or fire extinguishers spill-off into water streams can also be a source.

In the first TW Biomonitoring research in Slovakia (2023), the screening method using the FITC-T4 assay was applied to indicate PFAS activity in the **Brook Turňa (Turniansky potok)** waste stream near the cement kiln (Location: CK / 1). TW found elevated activity of 21 µg PFOA/l, which calls for further research. In 2024, TW expanded its PFAS research to natural water samples from the Slovak Karst National Park (Location Karst/2 and Karst water well/3), Zádiel water stream (Location: Za-c/ 4), Hrhov water well stream (Location: Hrhv/5), and the sample point of the **Brook Turňa** near Jablonov (Location: Jab / 6).

PFAS measurement through chemical analyses (LC-MS/MS) is minimal, as explained in TW's previous report (1st Biomonitoring 2023) on PFAS. In this research, TW applied an innovative PFAS CALUX method to these matrices. The promising PFAS CALUX method is also used by (semi) governmental water protection organisations in the Netherlands and the US to provide a more reliable overview of all possible PFAS. Based on the European Drinking Water Directive (EU) 2020/2184²⁰, **the Dutch government implemented a drinking water limit value of 100 ng per litre for 20 PFAS compounds, which will come into force by 12 January 2026.** The Dutch drinking water already complies with this limit value (van der Aa et al., 2022). In addition, the Dutch government expressed the intent to lower the legal drinking water limit value for PFAS to **4.4 ng PFOA eq./ litre (PEQ) in the future, based on EFSA guidelines.**²¹ The results from the PFAS CALUX bioassay are expressed as µg PFOA equivalent/ litre (µg PEQ/l) and have been corrected for the environmental background level of these samples, which is 0.14 µg PFOA eq./l for water and µg PEQ/g for other matrices, such as food, sediment, and vegetation.

Figure 30: PFAS results in natural water streams, May 8-11th, 2024

7.2.2. Heavy Metals in natural water streams

On three (3) water locations, heavy metals (14 elements) were analysed, as shown on pages 13 and 31. The results are expected in December and will be included in the 3rd TW Biomonitoring report.

7.3. Analysis results in Sediment

For the sediment samples taken on the five (5) locations on the map below, four (4) different analyses are performed. All these four (4) analysis methods for dioxins (DR CALUX), HM, chemical and assay analysis on PFAS (LC-MS/MS Σ 24 and PFAS CALUX) are implemented on the sediment sample taken in the **Brook Turňa (Turniansky potok)**, near the cement plant on 1100 m distance.

Figure 31: Results sediment analysis, May 2024

7.3.1. PFAS in Sediment

Sediment samples were taken from the **Brook Turňa (Turniansky potok)**, in the Slovak Karst National Park, near the cement plant. See all five (5) locations on the map in the figure on page 14. The result of the PFAS CALUX assay shows **1600 µg PFOA eq./g dm** in the **Turniansky potok** near the cement plant. The result is corrected with the environmental background level of 830 µg PFOA eq./g dm, measured in the Slovak Karst National Park. The lab results of the assay PFAS CALUX are given in micrograms per gram (µg PFOA eq./g), and for comparison reasons in Figure below expressed in µg/kg. The figure shows the gap between the “known” congeners by chemical analyses and the “unknown” PFAS congeners detected by the assay (PFAS CALUX). The chemical PFAS analysis shows the presence of **0.2 µg PFOS/kg dm** in the sediment near the cement kiln. This value is expressed as a lower bound (LB), meaning only results above the Limit of Quantification (LOQs) are considered.

7.3.2. Dioxins in Sediment

Analyses for this study are pending and will be included in the third biomonitoring report.

7.3.3. Heavy Metals in Sediment

At two reference locations in the Slovak Karst National Park, sediments are analysed for heavy metals. The results show much lower values than the analysis on soil in locations at a shorter distance of 3,5 km of the cement kiln. See also chapter and heavy metals 7.5.2. and in heavy metals on soil 7.1.1.3.

Figure 34: Results dioxin (PCDD/F/dl-PCB) in Pine needles (*Picea abies*)

On six (6) locations, as shown on page 16, samples of pine needles (*Picea abies*) were analysed for dioxins using the bioassay DR CALUX, as shown in the graphs below. The levels of dioxins in pine needles ranged from 0.48 – 3.03 pg TCDD eq./g (dm) with the bioassay DR CALUX in Dvorníky. In Zádiel, there was a 100% increase to 3.03 pg TEQ, while Hostovce showed an 83% decrease, from 2.86 to 0.48 pg TEQ/g dm. This represents the opposite trend of dioxins found in the eggs of backyard chickens at locations in Zádiel and Hostovce in 2023 and 2024 (see chapter 7.6. Results in Eggs of backyard chicken).

Figure 35: Dioxins in pine needles (*Picea abies*), May 8-11th 2024

The graphs below show that on six (6) out of seven (7) locations show exceeding results for the sum of dioxins (PCDD/F/dl-PCBs) in pine needles (*Picea abies*) when the EU limit of 0,75 pg/g TEQ in feed would be applied in case the pine needles are consumed as food. In the graphs, TW indicative code colours are used for vegetation, based on the EU limit of 0,75 pg TEQ/g for food.

Figure 36: Graphs of results dioxins in pine needles (*Picea abies*) for dioxins/furans (PCDD/F), dioxin-like PCBs (dl-PCBs) and the sum of dioxins (PCDD/F/dl-PCBs) with TW indicative colours for result interpreting.

7.4.2. Heavy Metals in pine needles

In 2024, concentrations of heavy metals were analysed at 7 locations in pine needles of the common native gymnosperm tree species, *Picea abies*. In Annex 2, comparisons are shown for heavy metals in soil, mosses (Bryophyta) and pine needles (*Picea abies*). Only barium (Ba), mercury (Hg) and zinc (Zn) in pine needles showed comparable results to those found in the mosses (Bryophyta), without exceeding those levels. TW analysed 14 heavy metals (HM) in the collected pine needles, and the results are shown in the next figure with 14 graphs, one for each heavy metal element. In the first TW biomonitoring research (October 2023), 14 heavy metals were analysed at two (2) locations, which are highlighted in square markings.

Pine needles from location 1A/B in the Slovak Karst National Park (SKNP) was provided by the official park rangers of the SKNP. Remarkably, high levels of cadmium (Cd), lead (Pb) and Tin (Sn) were found in this sample.

7.4.3. Polycyclic Aromatic Hydrocarbons (PAH) in Pine needles

Chemical analyses (GC-MS/MS) of PAH were performed on pine needles of *Picea abies* at seven (7) locations in the surrounding environment of the cement kiln, as shown in the map on page...

Figure 38: Results PAH in pine needles (*Picea abies*), May 8-11th 2024

The PAH results from the samples collected in May 2024 ranged from 48.1 – 207.5 µg Σ 16 PAH/g dm. Location seven (7), at Turňa nad Bodvou, showed **elevated levels of Phenanthrene and Fluorene, at 43.0 and 86.0 µg/kg dm, respectively**. The high concentration of fluoranthene is also confirmed by the Ekolive survey 2024 of soil samples in the eastern part of their study area.

Figure 39: PAH in Pine needles (*Picea abies*), May 8-11th 2024

Figure 40: PAH Σ 16 results in pine needles (*Picea abies*), May 8-11th 2024

Figure 41: PAH Σ 16 % in pine needles (*Picea abies*), May 8-11th 2024

As a reference, TW used pine needles (*Picea abies*) from the Slovak Karst National Park (SKNP), provided by the official (SKNP) rangers research/management team. **Remarkably, a high value of 6.7 μg Benzo(a)Pyrene/g was found at this reference location** in the Slovak Karst National Park. The reason for this elevation level of PAH in pine needles is unknown. It is possible that the physical landforms of the TW sample locations, which can be described as a bowl surrounded by mountains on three sides, play a role in the deposition of industrial emissions of substances of very high concern (SVHC). See the map in the figure below. The cement kiln is in the flat area of this bowl, bordered by mountains to the north, south and west, at a relatively short distance (18km) from the Slovak Karst National Park. It is unknown whether the steel industry near Košice, in the east, plays a role in the PAH and heavy metal contamination in the environment of this nature reserve, or whether it is related to its recent forest fires. The Ekolive study found concentrations of B[a]P of 740 $\mu\text{g}/\text{kg}$ in the east and north of their study area. Also notable are the high concentrations of B[a]P found in TW's 2nd biomonitoring study in mosses (Bryophyta) in SKNP (see the next chapter 8).

Figure 42: Physical landforms Slovak Karst National Park, area of 2nd TW Biomonitoring, May 2024

7.5. Results in Mosses

7.5.0. What are mosses (*Bryophytes*)?

Bryophytes are three groups of non-vascular land plants: mosses, hornworts, and liverworts. Each of these groups encompasses several hundred different species. Mosses are, in addition, the most important group within the non-vascular plants. **Non-vascular plants** are plants that **do not have a**:

1. **Xylem** transport system, for water/nutrient distribution from the roots upwards to the green leaves via cohesion and adhesion actions.
2. **Phloem** transport system, for energy/sugar-rich sap distribution, collected by chlorophyll cells from direct sunlight (photosynthesis) into the leaves, and then downwards to the root system and to all plant parts where energy or storage is needed.

Although Mosses lack these vascular transport systems, some mosses have more basic and simple vascular tissues that allow them to internally transport the water they collect by capillary action. When mosses first dry out, they do not die directly. First, the mosses turn brown and go dormant. Mosses can stay in this dormant state for various lengths of time before rehydration is necessary, depending on the species. Mosses are characterised by leaves that are only one cell wide, attached to a stem used for water and nutrient transportation. Mosses can absorb a substantial amount of water and have historically been used for insulation, water absorption, and as a source of peat.

Bryophytes are a group of plant species that reproduce via spores rather than flowers or seeds and are mostly found in damp environments. Like most green plants, mosses are mostly green in colour due to the chlorophyll pigments in the chloroplasts of plant cells, which are needed for photosynthesis, when they are not dehydrated.

In TW biomonitoring research, mosses from the *Bryophyta* group were sampled to examine by diverse whether the environment is contaminated with persistent organic pollutants, and POPs, like dioxins, PFAS, PAH and Heavy Metals.

7.5.1. Dioxins in Mosses (*Bryophytes*)

For this 2nd biomonitoring research, TW analysed moss samples (*Bryophyta*) from eight (8) locations for dioxins using the bioassay DR CALUX in the surrounding environment of the cement plant - Cementáreň Turňa nad Bodvou. For reference, moss samples (*Bryophyta*) were taken from more than 20 km waste of from the cement plant, near natural water springs in the mountains of the Slovak Karst National Park. These ecologically protected areas were visited for sampling with the guidance of official SKNP rangers.

The figure below shows the dioxin results for each location. The location numbers correspond to those numbers on the overview location map for mosses (*Bryophyta*) sampled in May 2024, on page 17.

Figure 44: Results of dioxins (PCDD/F/dl-PCB in mosses (*Bryophyta*), May 8-11th 2024

The value of mosses (*Bryophytes*) in biomonitoring environmental pollutants from industry is increasingly recognised.²² *Bryophytes* are frequently overlooked in biodiversity and ecosystem function assessments, even though they contribute significantly to ecosystem processes.²³ Moss data serve as an indicator of pollution levels but do not carry health thresholds. That is why a comparison was made with EU feed regulation to indicate at what level other food and feed can be contaminated.

TW measured dioxins using the bioassay DR CALUX in biomatrices such as mosses (*Bryophytes*) and pine needles (*Picea abies*) in the environment of the cement kiln. In the graph below, a comparison is shown between sampling in October 2023 and May 2024. The results show higher levels of dioxins in mosses in 2023 compared to those in May 2024. The levels of dioxins (PCDD/F) in mosses were **3.32 – 23.76 pg TCDD/TEQ/g dm in 2023** and **0.68 – 7.09 pg TCDD/ TEQ/g dm in 2024**.

²² Jovan S, et al. (2024). Putting biomonitors to work native moss as a screening tool for solid waste incineration. *Environ Monit Assess.* 2024 Nov 7;196(12): 1177..

²³ Slate, M.L., et al. (2024), Impact of changing climate on bryophyte contributions to terrestrial water, carbon, and nitrogen cycles. *New Phytol*, 242: 2411-2429. <https://doi.org/10.1111/nph.19772>

The cement plant - Cementáreň Turňa nad Bodvou is closed annually from December to February for at least 6 weeks for maintenance work. Photosynthesis of vegetation stops/slows down below 10 degrees C, which reduces the metabolic activity of plants, and so *Bryophyta* mosses as well.

Bryophytes produced more compounds, such as fatty acids and conjugates, carbohydrates, and glycosyls, phenylpropanoids and polyketides, flavonoids and anthocyanins in spring and summer than in autumn.²⁴ The capacity of saturation of fat-related compounds in the October sampling is more pronounced and can be the reason for higher levels of findings POPs in October 2023. Besides this hypothesis, the sampling time from February to May 8-11th is much shorter, only 3 months than the time in 2023 from February to the end of October, which is 9 months.

Figure 45: Results (sum) of dioxins (PCDD/F/dl-PCB) in mosses (*Bryophyta*), May 8-11th 2024

²⁴ Peters K, et al (2019). Chemical Diversity and Classification of Secondary Metabolites in Nine Bryophyte Species. *Metabolites*. 2019 Oct 11;9(10):222.

There is a more pronounced contribution of dl-PCB to the toxicity of dioxins in mosses in 2023. In eggs, where the chemical (GC-MS) analysis for dioxins could more specify the congeners, the dominant presence of PCB 126 is evident. This is a congener related to combustion.

Figure 46: Results dl-PCB in mosses (*Bryophyta*), May 8-11th 2024

In Figure 45, the results of dioxin (PCDD/F/dl-PCB) in mosses (*Bryophyta*) are given in the first graph for the 1st TW biomonitoring research in October 30-31st 2023 and 2nd in May on 8-11th 2024. The second graph shows the dioxin results for 2023/2024 per location. Sampling in May gives lower results but is still above the standard of 0.75 pg TEQ/g ds. As previously discussed, these lower values are explained by the fact that the sampling period after the winter stop of the cement kiln is considerably shorter.

Figure 47: Results sum of dioxins (PCDD/F/dl-PCB) in mosses (*Bryophyta*), May 8-11th 2024

7.5.2. Heavy metals in Mosses (*Bryophyta*)

The figure below shows the results of the 14 heavy metals analysed in mosses from seven (7) locations in the surrounding environment of the cement plant - Cementáreň Turňa nad Bodvou. For reference, TW collected three (3) samples from the protected area of Slovak Karst National Park (SKNP). See the location map, 5.4.2. for all ten moss (*Bryophyta*) samples on page 17.

As a screening tool, TW interprets the elemental content of moss mainly in relative, spatial terms (i.e., comparing where concentrations are relatively high vs. low) to help guide the need for more detailed research. Especially, the presence and/or deposition of heavy metals in mosses should prompt further investigation into its source(s). Since mosses lack a root system (See information on *Bryophytes* on page 49 (7.5.0.)), heavy metals in mosses are related to air deposition.

Figure 48: Results of heavy metals-14 in mosses (*Bryophyta*), May 8-11th 2024

The cement kiln conducts monitoring for heavy metal emissions: As, Pb, Cr, Co, Cu, Mn, and Ni in a summarised manner and Cadmium is monitored separately. There is no monitoring for the heavy metals Al, Ba, Hg, Ag, Tn, and Zn. This is notable because the combustion of rubber and car tyres as alternative fuel involves emissions of heavy metals like zinc (Zn), which comes from the presence of zinc oxide in tyres as part of the rubber vulcanisation. Increased emissions of Ni and Pb were observed in stack emissions when tyres were used as fuel.²⁵ The combustion of waste tyres produces atmospheric pollutants such as dioxins, dibenzofurans, NO_x, SO_x, and heavy metals such as Zn, Mn, Cr, and Pb in remaining ash, which present disposal issues.²⁶

TW monitors 14 heavy metals in vegetation: Ag, Al, As, Ba, Cd, Co, Cr, Cu, Hg, Mn, Ni, Pb, Sn and Zn. All these metals, except aluminium (Al), barium (Ba) and silver (Ag), are described in the BREF document for cement kilns.²⁷ As a screening tool, TW interprets the elemental content of moss mainly in relative, spatial terms (i.e., comparing where concentrations are relatively high vs. low) to help guide the need for more detailed research. Especially, the presence and/or deposition of heavy metals in mosses should prompt further investigation into its source(s). Since mosses lack a root system (See information on *Bryophytes* on page 49 (7.5.0.)), the presence of heavy metals in mosses is related to deposition from the air.

²⁷ Schorch F. et al (2013). *Best Available Techniques (BAT) Reference Document for the production of cement, Lime and Magnesium Oxide*. *Industrial Emissions Directive 2010/75/EU Integrated Pollution Prevention and control*

Monitoring of incinerator emissions is increasingly being conducted using mosses as bioindicators.²⁸ The ranking order of most heavy metals in mosses is as follows Zádíel> Včeláre> Hostovce> Dvorníky> Karst. The results indicated that monitoring soils and cultivated crops in the investigated area is necessary, as it may also be advised for the old mining region 50 km to the north. This area is already impacted by emissions from operating industries and is expected to expand production in the coming years. In the Figures below, heavy metal concentrations are expressed in mg/ kg dry weight (DW) for comparison with maximum levels for contaminants in food products (according to Slovak/European regulations) the concentration values are converted to mg/kg fresh weight (FW) or wet weight (ww). The maximum limits were derived from Musilová et al.²⁹ Heavy metals (HMs) can accumulate in the edible parts of plants, enter the food chain, and cause adverse toxicological effects to consumers. Their accumulation in vital organs such as the liver, kidneys, and bones can lead to many serious health disorders.

²⁹ Musilová, J., et al. (2024). Impact of old environmental burden in the Spiš region (Slovakia) on soil and home-grown vegetable contamination, and health effects of heavy metals. *Sci Rep* 12, 16371 (2022). 8

7.5.2.0. Heavy metals in vegetables

To compare the results of heavy metals in the mosses with the EU safety limits for vegetation and fruit and the average limits in Slovakia. This concerns the heavy metals: Aluminium (Al), Arsenic (As), Barium (Ba), Cadmium (Cd), Chromium (Cr), Copper (Cu), Lead (Pb), Mercury (Hg), Nickel (Ni).

The maximum levels (ML) for heavy metals in the vegetable set have been exceeded for Cu, Pb, and Hg for the levels found in the biomatrices of mosses. Two metals Copper (Cu) and Zinc (Zn) have a bioaccumulation factor higher than one, meaning they will accumulate heavy metals from the soil into the vegetation.

7.5.2.1. Silver (Ag)

Silver (Ag) is released into the environment through mining activities and the weathering of rocks. Anthropogenic sources of silver include cement manufacturing, cigarette tobacco, cloud seeding operations, coal combustion, smelting operations, steel and iron production, and urban refuse incineration. Silver concentration in mosses ranges from 0.011 mg/kg dm (reference in Slovak Karst National Park) and a maximum of 0.230 mg/kg dm measured in Včeláre.

Figure 50: Results Silver (Ag) in moss expressed in dry (dm) and wet weight (ww) in mg/kg

7.5.2.2. Aluminium (Al) in Mosses (*Bryophytes*)

The average aluminium (Al) concentration in vegetables like squash, carrots, marrow, cabbage, watercress and spinach is 27.5 mg/kg.³⁰ The Tolerable Weekly Intake (TWI) set by the European Food and Safety Authority (EFSA) is 1 mg/kg body weight/week.³¹ The aluminium (Al) levels found in the TW biomonitoring research (2023-2024) in mosses are extremely high.

Aluminium (Al) is one of the most common metals found in the environment, and consequently, in food. However, aluminium levels have been increasing over time due to anthropogenic activities. Aluminium is a known neurotoxic agent because it tends to accumulate in the brain. Several studies have reported the correlation between aluminium levels and diseases such as Alzheimer's disease.³² Aluminium also has the characteristic of interacting with the essential metals.³³

Figure 51: Results Aluminium (Al) in moss expressed in dry (dm) and wet weight (ww) in mg/kg

³³ <https://www.heraldopenaccess.us/openaccess/aluminium-exposure-through-the-diet>

7.5.2.3. Arsenic (As) in Mosses (*Bryophytes*)

The results for arsenic (As) in moss (*Bryophyta*) range from 2.7 – 18.0 mg/kg dm. The reference moss, collected in the Slovak National Park Karst, measured 0.17 mg/kg ds (dry substances) or dm (dry matter). The average arsenic level in vegetables is 0.05 mg/kg dm. There are differences in these arsenic levels between regular agriculture and private vegetable gardens. The transmission of arsenic from soil to vegetables depends on many soil quality parameters.

In the graph, arsenic levels in moss in the environment of the cement kiln are shown for 2023 and 2024. In Zádiel (Za-01), a concentration of 9.63 mg/kg wet weight (ww) is observed in this second biomonitoring research. Further research on the content of arsenic in vegetables in private gardens is needed. These TW results show a significant presence of arsenic in the environment of the cement kiln. Carcinogenic metals such as arsenic (As), cadmium (Cd), and chromium (Cr) can disrupt DNA synthesis and repair.

Figure 52: Results Arsenic (As) in moss expressed in dry (dm) and wet weight (ww) in mg/kg

7.5.2.4. Barium (Ba) in Mosses (*Bryophytes*)

Cement with barium is used as a binder with resistance to different types of radiation. Barium is widely used in manufactured materials such as tiles, automobile clutch and brake linings, rubber, brick, paint, glass, and other materials. Unusually high concentrations of this metal in soils may be a marker for anthropogenic activity. Barium is also abundantly present in waste.

Barium concentrations in the mosses of the environment of the cement kiln range from 23 – 325 mg/kg dm. The lowest value is measured in the Slovak Karst National Park, and the highest is in Zádiel. Urban garden leafy greens have a barium concentration of 45.7 mg/ kg dm, and root crops 21.5 mg/ kg dw.³⁴ There are no health-based standards for guidance values made for Ba in food crops. Therefore, the results reported here cannot be interpreted in the context of risk, however, barium levels in moss Northeast are elevated. In Zádiel, 14 times more than measured in SKNP. There is a lack of correlation between vegetable and paired soil concentrations for barium (Ba), which can be attributed to several important factors, including the strong effect of soil pH, organic matter content, and other soil properties on metal solubility and bioavailability.

Figure 53: Results Barium (Ba) in moss expressed in dry (dm) and wet weight (ww) in mg/kg

³⁴ McBride et al. (2015). *Environ Pollut*; 194: 254–261

7.5.2.5. Cadmium (Cd) in Mosses (*Bryophytes*)

The limit of Cadmium in the soil of vegetable gardens in the Netherlands is 0.6 mg/kg ds (NI), which is based on the transmission into vegetables. In leafy vegetables, the safe limit is 0.2 mg/kg ds (EU-limit) and for radishes, the maximum level is 0.020 mg/kg ds. Cadmium is a neurotoxic metal, and emission sources are related to combustion processes. The use of waste as an input material has increased the levels of cadmium, zinc, lead and cobalt found in cement.³⁵ **Elevations of cadmium, lead and zinc have polluted vegetables and soil in family allotment gardens due to mining and industrial activities.**³⁶ In the figure below, concentrations of cadmium were elevated in 2024, and high levels were found 2-3 km from the plant. The levels in mosses are compared with the EU regulations for cadmium in leafy vegetables.³⁷ The numbers in the right graph are expressed in wet weight for comparison. Findings of levels 10 times over the safe limit in vegetables can cause kidney failure, bone demineralisation, and an increased risk of cancer.³⁸ The tolerable weekly intake (TWI) for cadmium is 2.5 µg kg/bw. Inhabitants in this area consume many products from their gardens. Cadmium is nephrotoxic and causes renal tubular dysfunction, renal stone formation, and osteoporosis.

This finding of high levels of cadmium in moss in this area indicates a correlation between the activities of the cement kiln and the deposits of this industry in the nearby area. The study suggests that the consumption of vegetables cultivated in the environment of the cement kiln may pose a significant health risk to consumers.

Figure 54: Results Cadmium (Cd) in moss expressed in dry (dm) and wet weight (ww) in mg/kg

³⁸ Dziubanek, et al (2015). Contamination of food crops grown on soils with elevated heavy metals. *Ecotoxicol. Env. Saf.* 118, 183–189

7.5.2.6. Cobalt (Co) in Mosses (*Bryophytes*)

Levels of cobalt (Co) in the study area are 1.9 – 45.0 mg/kg dm and 1.7 – 33.7 mg/kg ww. The levels in the SNPK are 0.91 – 2.8 mg/kg dm and 0.2 – 0.9 mg/kg ww. Levels of Co are elevated in the research area. The consequences of elevated cobalt levels in vegetables are unknown. The findings highlight the need for continuous monitoring and research to prevent contamination and formulate guidelines for local food safety guidelines.

Figure 55: Results Cobalt (Co) in moss expressed in dry (dm) and wet weight (ww) in mg/kg

7.5.2.7. Chromium (Cr) in Mosses (*Bryophytes*)

Due to its wide industrial use, chromium is considered a serious environmental pollutant. The permissible value in plants is 1.3 mg/kg. The values in the graph are recalculated for wet weight. The chromium levels in the environment of the cement kiln exceed the limit for chromium in vegetables (1.3 mg/kg ww). In the literature, levels of chromium in vegetables from highly contaminated Cr soils are measured at 9.6 mg/kg.³⁹ In Včeláre and Zádiel, the permissible limit is surpassed by 34 resp. 28 times, respectively. Chromium (Cr) has been classified as a carcinogen by the International Agency for Research on Cancer. Cement dust exposure has a significant correlation with laryngeal cancer among workers exposed to cement dust in an epidemiological study.⁴⁰ Research found evidence that residents living near cement dust factories have an increased incidence of diseases linked to heavy metal toxicity.⁴¹

7.5.2.8. Copper (Cu) in Mosses (*Bryophytes*)

Copper (Cu), a toxic metal pollution found in the soil and water of industrialised areas, causes ongoing issues for agriculture product contamination and human health hazards. However, information on copper phytotoxicity and its accumulation in vegetables is largely unknown. Copper has a high bioaccumulation factor for vegetables. Copper levels in moss in the environment of the cement kiln range from 3.9 - 33.0 mg/dm. The reference levels of copper in the Slovak Karst National Park measure 3.9 – 8.6 mg/kg dm.

The EFSA establishes an Acceptable Daily Intake (ADI) of 0.07 mg copper/kg bw, equivalent to 5 mg Cu/day for adults. It should be noted that the term 'ADI' was not fully adequate for copper, which is a micronutrient essential for life. The term 'upper limit' in the nutrient area would be more appropriate. Therefore, in the specific case of copper, the ADI is considered equivalent to a UL.⁴² The average concentration of copper in food samples is 1.22 mg/kg ww.⁴³ The results of copper in mosses expressed in wet weight, 3.90 – 33.00 mg/kg ww (reference samples 1.8 – 2.3 mg/kg ww), are more than ten-fold higher in the environment of the cement plant.

Figure 57: Results Copper (Cu) in moss expressed in dry (dm) and wet weight (ww) in mg/kg

⁴³ Arnika (2019). Heavy metals in soils, foodstuffs, and human hair in the mining and metallurgical communities of Alaverdi and Akthala, Lori province of Armenia

7.5.2.9. Mercury (Hg) in Mosses (*Bryophytes*)

Mercury (Hg) is recognised as a toxic, persistent, and mobile contaminant that does not degrade in the environment and is the only element in the periodic table with its environmental convention, the Minamata Convention on Mercury. Mercury exposure can also reduce photosynthesis, transpiration rate, water absorption, and chlorophyll synthesis. Mercury is toxic to humans in all its primary forms, with the most toxic being methylmercury. The WHO considers mercury to be one of the top ten chemicals or groups of chemicals of major public health concern.

In Eastern Slovakia, there is a significant environmental burden from old mining activities, causing exceedances of the limit values for Hg, Cu, Zn, As, Cd, and Pb in soils. There have been warnings about the consumption of food due to high mercury levels. This area is about 30-50 km from the area of this research. The levels of mercury found in mosses in the environment of the cement kiln range from 0.036 -0.110 mg/kg dm and recalculated to fresh weight 0.030 – 0.090 mg/kg ww. This means that the found results for mercury exceed the maximum limit (ML) for tomatoes, and carrots, which is 0.03 mg/kg ww. In Dvorníky 200% and an exceedance of 300% in Včeláre. Only the reference samples in the SKNP comply with this maximum limit for mercury (Hg).⁴⁴

Figure 58: Results Mercury (Hg) in moss expressed in dry (dm) and wet weight (ww) in mg/kg

7.5.2.10. Manganese (Mn) in Mosses (*Bryophytes*)

Manganese is one of the major trace metals in ordinary Portland cement, which is mainly derived from alternative fuels and secondary raw feeds during the combustion process of clinker production. No monitoring program is applied for this heavy metal by the cement kiln. However, manganese emissions and deposition are related to incinerator processes (Rovira).⁴⁵ Long-term exposure to high levels of manganese can result in effects on the central nervous system such as visual reaction time, hand-eye coordination and hand steadiness. Exposure to higher levels over a long period can result in a syndrome known as manganism, which leads to feelings of weakness and lethargy, tremors and psychological disturbances. The accumulation of Mn occurs mainly in the basal ganglia and leads to a syndrome called manganism, whose symptoms of cognitive dysfunction and motor impairment resemble Parkinson's disease (PD). Various neurotransmitter systems may be impaired due to Mn, especially dopaminergic, but also cholinergic and GABAergic systems.

In this study, elevated levels of manganese in mosses are found in the environment of the cement kiln. The manganese concentrations in mosses in the study area are more than 10-fold higher than the levels of manganese in SNPK 18.7 – 74.20 mg/kg dm or 4.3 – 24.2 mg/kg ww. The graph shows high levels and urges further research on vegetables grown in the garden. Consumption of high manganese (Mn) concentrations can cause neurodegenerative disorders, cardiovascular toxicity, and liver damage.

Figure 59: Results Manganese (Mn) in moss expressed in dry (dm) and wet weight (ww) in mg/kg

7.5.2.11. Nickel (Ni) in Mosses (*Bryophytes*)

Nickel (Ni) is essential for proper plant growth and development. However, at high levels, nickel alters plant metabolic activities, and inhibits enzymatic activity, photosynthetic electron transport, and chlorophyll biosynthesis. Human exposure to nickel (Ni) mainly occurs through oral ingestion of water and food contaminated with nickel. Ni, as an immunotoxic and carcinogenic substance, can cause various health effects, including contact dermatitis, cardiovascular disease, asthma, pulmonary fibrosis, and respiratory cancer. The CONTAM Panel identified reproductive and developmental toxicity as the critical effect for the risk characterization of chronic oral exposure to Ni and established a tolerable daily intake of 2.8 µg Ni/kg body weight (bw) per day (EFSA) 46. Due to inter- and intra-individual variability, it is not possible to back-calculate the contribution of intake from food to Ni concentration. Average occurrences in vegetables and vegetable products (including fungi) ranged from 0.065 – 0.330 mg/kg.

Figure 60: Results Nickel (Ni) in moss expressed in dry (dw) and wet weight (ww) in mg/kg

⁴⁶ EFSA CONTAM Panel (EFSA Panel on Contaminants in the Food Chain), 2015. Scientific Opinion on the risks to public health related to the presence of nickel in food and drinking water. EFSA Journal 2015; 13(2):4002, 202 pp.

7.5.2.12. Lead (Pb) in Mosses (*Bryophytes*)

Lead is a naturally occurring element and is one of the longest-established poisons. Lead levels in mosses 2024 range from 0.4 – 272.0 mg/kg ww, expressed in dry matter 1.6 – 590.0 mg/kg dm. In Zádiel, the highest level of lead 272 mg/kg ww was found in mosses. The EU regulation for the maximum level (ML) of lead in food as vegetables is set at 0.1 mg/kg ww.⁴⁷ This ML implicates an exceeding of the maximum permitted limit for lead in mosses by a factor of 1000. All moss samples in the research area exceeded the maximum limit for lead in vegetables. Lead levels in moss of SNPK are: 1.6 – 8.8 mg/kg/dm and expressed in fresh weight 0.4 – 2.9 mg/kg ww. The current consensus is that no level of lead exposure should be considered “safe”. New evidence regarding blood levels at which morbidities occur has prompted to reduction of screening guidelines. Measurable cognitive decline (reduced IQ, academic deficits) has been found to occur, especially in children.⁴⁸ Lead (Pb) is a highly toxic element, bioaccumulative, and doesn't degrade easily metabolized in the environment. Food is a significant source of Pb exposure, and the potential risk to the population may stem from the bioaccumulation of Pb in edible vegetables. Lead exposure can cause plumbism, anaemia, nephropathy, gastrointestinal colic, and central nervous system symptoms. Neurological symptoms include ataxia, encephalopathy, seizure, swelling of the optic nerve, and disorder of consciousness. In the Netherlands, the government discourages the cultivation of consumer crops or recommends growing them only in containers to reduce exposure through consumption. The findings highlight the need for more precise monitoring to ensure a safe environment for the population.

Figure 61: Results Lead (Pb) in moss expressed in dry (dm) and wet weight (ww) in mg/kg

7.5.2.14. Zinc (Zn) in Mosses (*Bryophytes*)

Zinc (Zn), an activator of enzymatic reactions, is an indispensable trace element for plants and microorganisms. However, when the environmental levels of Zn exceed those required by plants or microorganisms, toxic effects can result. Atmospheric emissions of Zn from anthropogenic sources are an important source of Zn, which can then enter the human body by dispersion, deposition, assimilation by plants and transfer through the food chain. This can result in adverse human health effects. Additionally, excessive exposure to Zn from the ambient air can cause chronic bronchitis, peritonitis, emphysema, asthma and even lung cancer.⁵¹

Zinc is a heavy metal and is not monitored by the cement kiln, although zinc is predominantly present in waste streams and especially in car tyres. When tyres are burned, zinc will be emitted as a highly volatile metal. The average level of zinc in lettuce is 2.7 mg/kg ww and in spinach 6.1 mg/kg ww. The levels found in mosses in the environment of the cement kiln are 23.0 – 11.901.0 mg/kg dm or 20.4 – 6369.4 mg/kg ww. In the SNPK the levels of moss are 21.0 – 32.0 mg/kg dm or 4.9 – 10.4 mg/kg ww.

Figure 63: Results Zinc (Zn) in moss expressed in dry (dm) and wet weight (ww) in mg/kg

⁵¹ Li, Z.; Huang, Y.; Li, X.; Wang, G.; Wang, Q.; Sun, G.; Feng, X. Substance Flow Analysis of Zinc in Two Preheater–Precalciner Cement Plants and the Associated Atmospheric Emissions. *Atmosphere* 2022,13,128. <https://doi.org/10.3390/atmos13010128>

7.5.2.15 Physical landforms and wind patterns

Moss location Dvorníky 03 (Dv-03) is located at 1050 m distance to the North of the cement plant. It is a small hill (around 100 m in height), covered with native deciduous and gymnosperm (coniferous) trees, mosses, shrubs and flowers. This green coverage of trees and plants, which is secluded in the graveyard as well, might protect the plants on the ground from the deposition of POPs by wind streams. The results of the heavy metals in the mosses of this location (Dv-03) are comparable with the results of the mosses of the reference locations in the Slovak Karst National Park > 20 km distance to the West. Hypotheses could be that land covered with trees, such as native forest or planted with gardens and (cemetery) parks, as well as slopes not oriented towards the main wind direction, protect from POP contamination of the surrounding area, depending on the prevailing wind direction and fumigation due to the specific physical landforms of an area.

Figure 64: Wind behavior in specific physical landforms Zádíel

Location Zádiel 01 (Za 01) shows very high values of heavy metals in the mosses (Bryophyta), like locations Vc-01 and in somewhat lower values also on Dv-01, these are all located North/West from the cement kiln, on a short distance (<3,5 km). On the moss three (3) locations further to the West (>20 km) in Slovak Karst National Park, the mosses show very low values of heavy metals and can be therefore seen as real reference samples. The reason location Zádiel 01 (Za-01) show high values of heavy metals in mosses (Bryophyta) could be the northern location. Mosses were collected near a barn, made from iron plates under the roof covering, on a long, small strip of soil covered with stone pebbles with no gutter attached. Rainwater from the roof is absorbed by mosses on the ground.

Location Zádiel 02, (Za-02) is 200 m on the other side of the road, with a long garden to the East. Mosses (Bryophyta) were collected from stone roof tiles which covered the small wooden shed on the North side of it. The garden is surrounded by high old (orchard) trees. This could be the reason for lower values of heavy metals measured at this location.

Figure 65: Moss (Bryophyta) Zádiel 01 and 02

7.5.3 PAH in mosses (*Bryophyta*)

In the various national and EU regulations of PAHs, the summation of concentrations of 4 or 10 PAH substances is adopted. The table in chapter 6.2. on page 25, shows the different relative toxicity values expressed as relative potency (REP) factors. For example, Benzo[b]fluoranthene, the most toxic PAH, is 10,000x more toxic than anthracene. This clearly shows that simply adding up the concentrations of PAH congeners is by no means enough to show the actual toxic load. The regulations need to be updated. An additional problem, which is also present with other highly hazardous substances, is that the analytical possibilities are extremely limited. Out of about 4-700 different PAH substances, only 16 can be analysed with a chemical analysis method GC-MS/MS, see Figure 21, while the brominated, chlorinated or any other substitutions are not being examined. In the figure below the 16 different PAH substances are shown and ordered by the number of benzene rings in their PAH molecular structure.

In 2024, PAH concentrations in mosses range from 109.9 - 5530.5 mg Σ 16PAH/kg dm. The increase in Host'ovce from 1065.6 mg Σ 16PAH/kg dm in 2023 to 5530.5 mg Σ 16PAH/kg dm in 2024 is striking. There has been no change in the property of this location, nor has fire or burning occurred. The graph below shows the increases of the different congeners. Especially prominent is the increase in the concentration of Benzo[a]pyrene (B[a]P).

Figure 66: Benzo[a]pyrene in mosses

The graph below shows the increases of the different congeners. Especially prominent is the increase in the concentration of Benzo(a)pyrene (B[a]P) to 1600 mg Σ 16PAH/kg. Also, Benzo(a)fluoranthene is with 2100 mg Σ 16PAH /kg ds prominent present.

Figure 67: PAH-16 in mosses (Bryophyta)

7.5.4. PFAS in mosses

In 2024, six moss samples were negative for PFAS. No PFAS above the LOQ could be detected. One moss sample in Včeláre measured 0.6 μg PFTrDA/kg dm. This PFAS congener is six times found in eggs. Further screening with the chemical analyses of >4 PFAS and the application of PFAS CALUX bioassay is recommended to address the potential underestimation of PFAS contamination in this area.

Figure 68: PFAS in mosses

7.6. Results in Eggs of backyard chicken

Figure 69: Egg sample locations

7.6.1. Dioxins in Eggs

In the 1st TW biomonitoring research of October 2023, high levels of dioxins were found in eggs from backyard chickens at three locations using the bioassay DR CALUX. The highest dioxin level of 9.8 pg BEQ/g fat in 2023 was found at **Zádiel (Za-02)** in 2023. In this 2nd research (May 2024), the dioxin level at the same location Za-02 was slightly reduced by 23% to **7.50 pg BEQ/g fat**. However, it still exceeds the EU limit of 3.3 pg BEQ/g fat, as shown in the figure below. At the **Hostovce (Hs-01)** location, dioxin levels have increased by 83% to **8.6 pg BEQ/g fat**. At two (2) other locations, Dvorníky and Včeláre, dioxin levels increased by 358% to 5.50 pg BEQ/g fat. At Zádiel-01, further south, no dioxin levels above the EU limit were measured.

Figure 70: Dioxins in eggs of backyard chicken

An exceedance of the EU regulation for bioassay results with the DR CALUX (3.3 pg BEQ for the sum of PCDD/F/dl-PCB), mandates chemical analysis on six egg samples. The results of these measurements are shown in the graph below. The dioxin level at Zádíel exceeds the EU limit by 5.4 pg TEQ/g fat and should not be consumed. The chemical analysis shows lower TEQ levels than the bioassay of DR CALUX due to the omission of measurement of other substances with dioxin-like properties, such as brominated dioxins. See the chapter above for further details. The correlation between the DR CALUX and GC-MS results to EU regulations is explained by Hoogenboom et al.⁵²

Figure 71: Dioxins (GC-MS) in eggs of backyard chicken

Remarkable is the higher value of dl-PCB measured in Hostovce by the bioassay. The graph below clearly shows that the PCDD/F levels are always higher than the chemical analysis for dioxins. This is a strong indication that more dioxins are present in the eggs than can be measured by the limited chemical analysis.

Comparatively, the understanding and study of other unintentionally generated POPs (such as dl-PCBs and polybrominated dibenzo(p)dioxins and furans (PBDD-Fs)) from cement plants are not as well documented and may be more difficult to measure due to either their lack of presence in the flue gas or the analytical ability to detect them. Even if a plant performs to its engineered conditions to achieve stoichiometric combustion, the reality is that incomplete combustion and pollutant formations do occur.⁵³

⁵² Hoogenboom LAP et al. (2010). Revised EU-criteria for applying bioanalytical methods for screening of feed and food for dioxins and dioxin-like PCBs, *Organohalogen Compounds* Vol. 72, 1800-1905 (201)

⁵³ Richards G. and Igor E. Agranovski I.E. (2017), Dioxin-like pcb emissions from cement kilns during the use of alternative fuels, *Journal of Hazardous Materials*, Volume 323, Part B, Pages 698-709, ISSN 0304-3894,

Figure 72: Comparison of chemical analyses and bioassay analyses on PCDD/F/dl-~PCB

Figure 73: Comparison of chemical analyses and bioassay analyses on PCDD/F and dl-~PCB separately

In the case of waste co-incineration, catalogue number 16 01 03 (worn tyres) are also recovered by the activities of R4 and R5, as the metal part of the tyre (steel cord, approximately 40% of the weight of the tyre) melts at high temperatures in the rotary kiln and becomes part of the resulting clinker product or cement. The levels of the two furans pentachlorodibenzofuran and hexachlorodibenzodifuran are prominently present at the locations of Dvorníky and Zádiel. In the study by Richards, a statistical predominance of the 1,2,3,7,8-PeCDF and 1,2,3,4,7,8-HxCDF congeners was found about combustion of alternative fuels like tyres, PCB-oil and plastic. When these two furans are placed on the maps with indicative colours a clear pattern can be observed. The chemical (GC-MS) analyses on dioxins in eggs of backyard chickens shows clearly the presence of the characteristics of these typical combustion congeners, just in the village of Dvorníky.

Figure 74: Pentachlorodibenzofuran (1,2,3,7,8-PeCDF) in eggs of backyard chicken

Figure 75: Hexachlorodibenzodifuran (1,2,3,4,7,8-HxCDF) in eggs of backyard chicken

The spatial deposition mapping of PCB 126, the most toxic dioxin-like PCB, show another pattern. The emission of PCB 126, as well as the other non-ortho PCB 169, is related to incomplete combustion. The high levels of dioxins and PCB 126 at Zádíel are likely caused by the geographical characteristics of that area, forming a bowl-like structure where emissions can be deposited more concentrated in the environment. The high levels of PCB 126 is remarkable and need to be researched further.

Figure 76: PCB 126 in eggs of backyard chicken

7.6.2. Heavy metals in eggshells

For this second TW biomonitoring research (May 8-11, 2024) eggshells were taken from four (4) egg locations and one (1) reference location (blue bar/green square, ref. mark) from a colony of wildlife birds of the species Heron (Ardea), living near Lake Hrhov (Hrhovské rybníky), near Slovak Karst National Park, as shown on the location map on page 19. These five (5) eggshell samples were analysed for 14 heavy metals. In the first biomonitoring research, eggshells from one location (Dv-02) were analysed for 14 heavy metals. Heavy metals were also determined in the eggshells. Besides the eggshells of backyard chickens, TW took reference eggshells from Herons at the Lake Hrhov (Hrhovské rybníky). The high levels of aluminium and barium in the eggshells of herons were remarkable. At the time of sampling, several herons had fallen from the trees, including young ones. Additional results from other countries have been included to provide context and help interpret these findings. Cadmium (Cd), chromium (Cr), cobalt (Co), manganese (Mn), mercury (Hg), silver (Ag) and tin (Sn) could not be measured above the limit of quantification (LOQ). High results of Zinc (Zn) and Nickel (Ni) are found in the eggshells of the wildlife Heron (Ardea).

Figure 77: Heavy metals in eggshells

7.6.3. PFAS in Eggs backyard chicken

PFAS analyses were carried out on the eggs. PFOS was measured in all eggs. In eggs from Turňa nad Bodvou, six (6) different PFAS congeners were detected. In 2023, the highest PFAS concentration was found in Zádiel. In 2024, PFAS concentrations decreased; however, all eggs from backyard chickens were positive for PFAS. The graph below also shows the results from ECB. The difference is that TW uses PFAS analysis on 24 congeners, whereas ECB only analyses four (4) PFAS congeners.

Figure 78: PFAS in eggshells

7.7 Results in Meat of wildlife deer, Carp fish and domestic cow

Figure 79: Results in meat wildlife deer, carp fish and domestic cow

7.7.1. Dioxins in Meat of (wildlife) animals / mammals

In this second TW biomonitoring, wildlife meat samples from Carp fish (*Cyprinus carpio*) and deer from the nearby forest in the western direction of Včeláre were provided for analysis. The Carp, approximately 2-3 months old, was caught in the waters of Lake Hrhov (Hrhovské rybníky), according to the fisherman's information. The deer, also approximately 2-3 months old, had its meat provided by a local farmer from Včeláre. The calf was approximately 2-3 months old. The bioassay DR CALUX for analysis on dioxins, showed that only dioxin-like PCB was found in the cow, as shown in the table in the figure below.

Figure 80: Dioxins in fish, deer and cow

7.7.2. PFAS in wildlife Carp fish

Some substances in the PFAS family are very carcinogenic at very low concentrations while spreading fast and widely throughout the environment. These substances of very high concern (SVHC) are extremely persistent and known as 'Forever Chemicals'. The consumption of 'fish and fish products' is one of the most contaminated food groups with PFAS. ToxicoWatch analysed the freshly caught meat and liver of Carp fish (*Cyprinus carpio*) from the natural waters of Lake Hrhov (Hrhovské rybníky) on PFAS with chemical analyses of Σ 24 PFAS substances. The results for PFAS in the Carp liver detected 0.2 PFOS/g dm.

See also section 7.2.1. for the explanation about PFAS in water streams.

2nd TW Biomonitoring in the environment of cement plant - Cementáreň Turňa nad Bodvou, May 2024

8. Counter research

8.1 Comparison research Danucem Slovensko (ECB)

Danucem Slovakia a.s., owner of the cement plant Cementáreň Turňa nad Bodvou, ordered Ekotoxikologické centrum Bratislava s.r.o. (ECB) to undertake research on eggs of backyard chickens in the environment of the cement kiln. The eggs from 11 locations were sampled from a broader area than the research radius of 2,5 km radius applied by TW. At the site near Bratislava, Bernolákovo, a reference collected by ECB shows levels of dioxins of 0.06 pg TEQ/g fat for the sum of dioxins, which is comparable to supermarket eggs. The results of this study are compared with the results of TW's 1st and 2nd biomonitoring studies. In the graphs below, four (4) locations can be compared. The results have a similar qualitative outcome: eggs in the environment of the cement kiln are contaminated with dioxins, but quantitatively, there are remarkable differences. In **Dvorníky**, the difference factor is **2.8**, **Zádieľ** **5.6** and **Hostovce**, shows a factor of **7.2** in the outcome of the chemical analyses for dioxins. Eggs sampled in Smolník, 17.2 km from the cement kiln, show extremely high dioxins at 75.9 pg TEQ/g fat and a dl-PCB content of 58.86 pg TEQ/g fat. Such values are exceptional and encountered in developing countries and warrants immediate action of this serious contamination. The result at Smolník can be considered as an outlier and highlights the difficulty of finding locations without any confounding factors, as can be found in Eastern Slovakia from old mining activities in regions relatively near Smolník.⁵⁴

Figure 84: Comparison results ECB and TW

⁵⁴ Musilová, J., Franková, H., Lidiková, J. et al. Impact of old environmental burden in the Spiš region (Slovakia) on soil and home-grown vegetable contamination, and health effects of heavy metals. *Sci Rep* 12, 16371 (2022). <https://doi.org/10.1038/s41598-022-20847-8>

8.1.2. Counter research Košice Regional Government (Ekolive)

On behalf of the Kosice Regional Government, Ekolive surveyed the environmental surrounding area of the cement plant - Cementáreň Turňa nad Bodvou. Eighty-one (81) samples were analysed for soil, tree bark, mosses and two (2) eggs from backyard chickens. The analyses were performed for dioxins (chemical GC-MS), PAH (Chemical: GC-MS/MS on Σ 16 PAH) and heavy metals.

In terms of dioxins, this research confirms the pressure of these toxic substances in the environment of cement plant - Cementáreň Turňa nad Bodvou. In soil, Ekolive did not find exceeding of dioxins, however, high levels of dioxins were found in biomass as mosses and tree bark. The Košice Regional Government (by Ekolive) confirm the findings of TW of increased dioxins in backyard chicken eggs.

Concerning the heavy metals, TW cannot agree with the conclusion that the soil complies with the Slovak rules for heavy metals, as the limits applied are intended for industrial purposes. No safety rules have been implemented to protect the health of inhabitants living in the surrounding villages and areas. Many people grow vegetables in their gardens, and they should be able to rely on the safety of their food. Likewise, children should have access to playgrounds with soil which does not pose health risks. In the Netherlands, when it comes to the healthy growth of vegetables in a vegetable garden, any increase in the background value of a heavy metal is considered an alarm signal. Based on this principle, the levels of 14 metals detected by TW indicate a problem for the environment. The mosses biomatrices exceed in this study exceed limits EU limits for food many times over. The use of mosses (*Bryophyta*) as a biomarker is becoming more prevalent and would be appropriate for the Kosice Regional Government and/or the cement industry to apply it on a structural basis. It shows that analysis of soil alone gives limited insight into the toxic load of an environment. Multiple parameters are most certainly needed such as biomonitoring in biomass

TW Recommendations for cement kiln emissions in Turňa nad Bodvou:

- Semi-continuous measurements are necessary to monitor actual emissions, as the current short term of measurement represents only 0.2% per year.
- Independent organisations should conduct these cement kiln industry emission measurements.
- Transparency in the publication of emission data from the cement kiln, i.e. not corrected averages, just real-time data of production and incidents.

TW endorses these recommendations of Ekolive in the interest of the health of people living near industries like the cement kiln. In addition, biomonitoring should also be applied to the monitoring of mining of limestone and dust emissions during, production, transport, and use of products (cement) and end-of-life product disposal.

Figure 85: EU regulation dioxins for waste incinerators

9. Conclusions 2nd TW biomonitoring May 2024

From May 8-11, 2024, sixty-three (63) samples of eggs/eggshells of backyard chickens, wildlife meat from deer, Carp fish (*Cyprinus carpio*), wildlife bird eggshells from Heron (*Ardea*), mosses (*Bryophyta*), pine needles (*Picea abies*), water from natural water stream and wells, sediment from natural water streams and wells, and soil were collected by the TW team.

Key Findings of this 2nd TW biomonitoring:

Soil:

1. **Heavy Metals (14):** Seriously contaminated soil with lead (Pb), **110 mg/kg** and Arsenic (As) **48 mg/kg** at the children's playground in Dvorníky-Včeláre at a short distance from the cement kiln.

Water, natural streams:

2. **PFAS:** High value of PFAS with assay PFAS CALUX is found **1600 µg PFOA eq./g dm** measured in the Brook Turňa (potok Turňa) water stream.

Sediment:

3. **Heavy Metals (14):** The results of heavy metals in sediment on the reference locations in the Slovak Karst National Park at > 20 km West of the cement plant show lower values than the results of heavy metals in soil on the seven (7) locations within a short distance of 3,5 km from the cement kiln.
4. **PFAS:** The chemical PFAS analysis shows the presence of **0.2 µg PFOS/kg dm** and with PFAS CALUX **no PFAS is found on the reference locations** in Hrhov, Jablonov and Blatný potok brook in Zádiel.

Vegetation / Pine needles (*Picea abies*):

5. **PAH:** The PAH results of the pine needle samples collected in May 2024 are between **48.1 – 207.5 µg Σ 16 PAH/g dm**. Location seven (7), at Turňa nad Bodvou, shows **elevated levels of Phenanthrene and Fluorene, resp. 43.0 and 86.0 µg/kg dm**.
6. **PAH:** Specific combustion-related (4 and 5 rings) PAH congeners, such as Benzo[a]pyrene, are found in mosses (*Bryophyta*) and pine needles (*Picea abies*) in the surrounding area of the cement kiln. Remarkably also in pine needles (*Picea abies*) at one location in the protected area of Slovak Karst National Park.
7. **Heavy Metals (14):** high results of lead (Pb), Cadmium (Cd) and Tin (Sn) are found in the pines of the Slovak Karst National Park.
8. **Dioxins:** Six (6) out of seven (7) pine needle locations show results **exceeding the EU-limit of 0,75 pg/g TEQ for feed** for the sum of dioxins (PCDD/F/dl-PCB), in case pine needles are consumed like vegetables/feed.

Vegetation / Mosses (*Bryophyta*):

9. **Dioxins:** The results show higher values for dioxins in mosses in 2023 than the samples in May 2024. The levels of dioxins (PCDD/F) in mosses were **3.32 – 23.76 pg TCDD/TEQ/g dm in 2023** and **0.68 – 7.09 pg TCDD/TEQ/g dm in 2024**. The cement kiln is closed annually from December to February for at least 6 weeks for maintenance work. In 2024 the sampling time from February to May 8-11th was much shorter, than the nine months in 2023. Besides that, photosynthesis of vegetation stops/slows down below 10 degrees C, which reduces the metabolic activity of plants, and so *Bryophyta* mosses as well.
10. **Dioxins:** The results of dioxins in mosses (*Bryophyta*) and pine needles (*Picea abies*) are elevated compared to reference data.

11. **Heavy Metals (14):** all mosses (*Bryophyta*) locations show elevated levels of heavy metals compared to the levels in the reference location in Slovak Karst National Park.
12. High concentrations of heavy metals are found on mosses (*Bryophyta*), at North/West locations near the cement kiln, indicating serious contamination of the soil of private vegetable gardens. The specific physical landforms of the valley, surrounded by steep mountains on both sides with the gap in it of the Zádiel Gorge (Zádielska dolina) could cause specific wind fumigation.

Eggs of backyard chicken:

13. **Dioxins; Exceeding values** for dioxins of the **EU limit of 3.3.pg BEQ/g/fat (Dr CALUX) and 5.0 TEQ/g fat (GC-MS)** in the eggs of backyard chickens are found.
14. Specific dioxin patterns (**congeners**) in eggs **indicate a source of co-incineration of alternative industrial fuel.**
15. **PAH:** The specific **congener patterns** of dioxins (PCDD/F/dl-PCB) and polycyclic aromatic hydrocarbons (PAH Σ 16) in the eggs of backyard chickens and vegetation show **elevated levels of combustion-related contamination.**
16. **PFAS:** with chemical analysis, LC-MS/MS on Σ 24 PFAS substances show **contamination at all eggs of backyard chicken locations.**

Eggshells backyard chicken and wildlife bird Heron (*Ardea*)

1. **Heavy Metals:** Remarkable are the **highest levels of aluminium (Al), zinc (Zn) and nickel (Ni) in the eggshells** of a wildlife bird Heron (*Ardea*) population near the Lake Hrhov (Hrhovské rybníky)

Meat of wildlife deer, Carp fish, domestic cow:

2. **PFAS:** Contamination of **PFOS** by chemical PFAS analysis (LC-MS/MS Σ 24) in the liver of Carp fish (*Cyprinus carpio*), from Lake Hrhov (Hrhovské rybníky).

Counter research:

3. Danucem Slovensko a.s., (by Ekotoxikologické centrum Bratislava, ECB) confirms the findings of TW of increased dioxins in backyard chicken eggs, although differences in results and interpretation were apparent.
4. The Košice Regional Government (by Ekolive) confirm the findings of TW of increased dioxins in backyard chicken eggs. It shows that analysis of soil alone gives limited insight into the toxic load of an environment. Multiple parameters are most certainly needed such as biomonitoring in biomass.

These findings are a clear call for action for the responsible authorities to take immediate action to ensure the safety of people living in the surrounding area of the cement plant. Authorities must prioritise the elimination of harmful POP industrial emissions. The precautionary principle should guide their efforts to address these significant environmental and public health concerns.

ICP-MS zwaremetalen	Chroom (Cr) Q	mg/kg DS	24
ICP-MS zwaremetalen	Koper (Cu) Q	mg/kg DS	22
ICP-MS zwaremetalen	Kwik (Hg) Q	mg/kg DS	0.13
ICP-MS zwaremetalen	Nikkel (Ni) Q	mg/kg DS	27
ICP-MS zwaremetalen	Lood (Pb) Q	mg/kg DS	39
ICP-MS zwaremetalen	Tin (Sn) Q	mg/kg DS	1.6
ICP-MS zwaremetalen	Zink (Zn) Q	mg/kg DS	182

* informatie verkregen van de klant
M.O. = Meetonzekerheid.

Toelichting Revisie

Door het laboratorium is parameter Al toegevoegd.

Normec Groen Agro Control is ingeschreven in het register van de Raad voor Accreditatie voor testlaboratoria onder nr. L335 conform ISO/IEC 17025. De met 'Q' gemarkeerde parameters zijn onder accreditatie geanalyseerd. Details over de gebruikte methoden en meetonzekerheid per parameter zijn beschikbaar op aanvraag.
Dit rapport mag zonder schriftelijke toestemming niet anders dan in zijn geheel worden gereproduceerd.

M.O. = Meetonzekerheid.

Normec Groen Agro Control is ingeschreven in het register van de Raad voor Accreditatie voor testlaboratoria onder nr. L335 conform ISO/IEC 17025. De met 'Q' gemarkeerde parameters zijn onder accreditatie geanalyseerd. Details over de gebruikte methoden en meetonzekerheid per parameter zijn beschikbaar op aanvraag.
Dit rapport mag zonder schriftelijke toestemming niet anders dan in zijn geheel worden gereproduceerd.

Information about report

The results of examination refer exclusively to the checked samples.

Results are given in table 1.

Sample characteristics are given in table 2.

The measurement uncertainty for CALUX method is typically below 30%. For the calculation a coverage factor of 1 is used.

If an analysis is accredited by ISO17025 (RvA L401) is indicated by a yes or a no

Start date of the test: 18-06-2024

End date of the test: 18-07-2024

For the method DR CALUX and the sum parameter PCDD/PCDF (separated TEQ) the used method is extraction with organic solvents; the extracts are cleaned on an acid silica column and separation is done with a florisil column. The cleaned extracts are dissolved in DMSO. The DR CALUX activity is determined (24h exposure) and benchmarked against 2,3,7,8-TCDD. The DR CALUX analysis is done according to p-bds-051

For the method DR CALUX and the sum parameter dl-PCBs (separated TEQ) the used method is extraction with organic solvents; the extracts are cleaned on an acid silica column and separation is done with a florisil column. The cleaned extracts are dissolved in DMSO. The DR CALUX activity is determined (24h exposure) and benchmarked against 2,3,7,8-TCDD. The DR CALUX analysis is done according to p-bds-051.

For the method DR CALUX and the sum parameter PCDD/PCDF (BEQ; semi) the used method is shake extraction with organic solvents (hexane); the extracts are cleaned on an acid silica column. The cleaned extracts are dissolved in DMSO. The DR CALUX activity is determined (24h exposure). The response of the sample is corrected for the background and subsequently corrected for the apparent bioassay recovery with a reference sample at the level of interest. The evaluation was done on the maximum level for PCDD/F, from which a cut off value has been established (2/3 of maximum level) to determine if a sample is compliant or suspected. As a maximum level the level of the matrix as described in the table above is used. After the evaluation an estimation is given of the sample in the form of a BEQ outcome. The DR CALUX analysis is done according to p-bds-051.

For the method DR CALUX and the sum parameter PCDD/PCDF and dl-PCBs (BEQ; semi) the used method is shake extraction with organic solvents (hexane); the extracts are cleaned on an acid silica column. The cleaned extracts are dissolved in DMSO. The DR CALUX activity is determined (24h exposure). The response of the sample is corrected for the background and subsequently corrected for the apparent bioassay recovery with a reference sample at the level of interest. The evaluation was done on the maximum level for PCDD/F and dl-PCBs, from which a cut off value has been established (2/3 of maximum level) to determine if a sample is compliant or suspected. As a maximum level the level of the matrix as described in the table above is used. After the evaluation an estimation is given of the sample in the form of a BEQ outcome. The DR CALUX analysis is done according to p-bds-051.

All DR CALUX analysis results comply with EU requirements as indicated in Commission Regulation (EU) 2017/644 of 5 April 2017 laying down methods of sampling and analysis for the control of levels of dioxins, dioxin-like PCBs and non-dioxin-like PCBs in certain foodstuffs. Maximal levels according to Commission Regulation (EC) No 2023/915.

Date report (dd-mm-yyyy):

17-10-2024

Information about report

The results of examination refer exclusively to the checked samples.

Results are given in table 1.

Sample characteristics are given in table 2.

The measurement uncertainty for CALUX method is typically below 30%. For the calculation a coverage factor of 1 is used.

Accreditation ISO 17025 (RvA L401) is not applicable for activities described in this report

PFAS LCMSMS	Perfluor-1-octaansulfonzuur (PFOS) Q	µg/kg	0.14
PFAS LCMSMS	Perfluor-n-octaanzuur (PFOA) Q	µg/kg	<0.1
PFAS LCMSMS	Perfluor-n-nonaanzuur (PFNA) Q	µg/kg	<0.1
PFAS LCMSMS	Perfluor-1-hexaansulfonzuur (PFHxS) Q	µg/kg	<0.1
PFAS LCMSMS	Som van PFOS, PFOA, PFNA en PFHxS	µg/kg	0.14
PFAS LCMSMS	Perfluor-n-butaanzuur (PFBA) Q	µg/kg	<0.5
PFAS LCMSMS	Perfluor-n-pentaanzuur (PFPeA) Q	µg/kg	<0.1
PFAS LCMSMS	Perfluor-n-hexaanzuur (PFHxA) Q	µg/kg	<0.1
PFAS LCMSMS	Perfluor-n-heptaanzuur (PFHpA) Q	µg/kg	<0.1
PFAS LCMSMS	Perfluor-n-decaanzuur (PFDA) Q	µg/kg	<0.1
PFAS LCMSMS	Perfluor-n-undecaanzuur (PFUnDA) Q	µg/kg	<0.1
PFAS LCMSMS	Perfluor-n-dodecaanzuur (PFDoA) Q	µg/kg	<0.1
PFAS LCMSMS	Perfluor-n-tridecaanzuur (PFTeDA) Q	µg/kg	<0.1
PFAS LCMSMS	Perfluor-n-tetraecaanzuur (PFTeDA) Q	µg/kg	<0.1
PFAS LCMSMS	Perfluor-1-butaansulfonzuur (PFBS) Q	µg/kg	<0.1
PFAS LCMSMS	Perfluor-1-heptaansulfonzuur (PFHpS) Q	µg/kg	<0.1
PFAS LCMSMS	Perfluor-1-decaansulfonzuur (PFDS) Q	µg/kg	<0.1
PFAS LCMSMS	Perfluor-1-dodecaansulfonzuur (PFDoS) Q	µg/kg	<0.1
PFAS LCMSMS	Perfluor-1-nonaansulfonzuur (PFNS) Q	µg/kg	<0.1
PFAS LCMSMS	Perfluor-1-pentaansulfonzuur (PFPeS) Q	µg/kg	<0.1
PFAS LCMSMS	4:2 Fluortelomeersulfonzuur (4:2FTS) Q	µg/kg	<0.1
PFAS LCMSMS	6:2 Fluortelomeersulfonzuur (6:2FTS) Q	µg/kg	<0.1
PFAS LCMSMS	8:2 Fluortelomeersulfonzuur (8:2FTS) Q	µg/kg	<0.1
PFAS LCMSMS	Hexafluorpropyleenoxide dimeer zuur (HFPO-DA of GenX) Q	µg/kg	<0.1

* informatie verkregen van de klant

Normec Groen Agro Control is ingeschreven in het register van de Raad voor Accreditatie voor testlaboratoria onder nr. L335 conform ISO/IEC 17025. De met 'Q' gemarkeerde parameters zijn onder accreditatie geanalyseerd. Details over de gebruikte methoden en meetonzekerheid per parameter zijn beschikbaar op aanvraag.
Dit rapport mag zonder schriftelijke toestemming niet anders dan in zijn geheel worden gereproduceerd.

Information about report

The results of examination refer exclusively to the checked samples.

All analysis results comply with EU requirements as indicated in Commission Regulation (EU) 2017/644 of 5 April 2017 laying down methods of sampling and analysis for the control of levels of dioxins, dioxin-like PCBs and non-dioxin-like PCBs in certain foodstuffs. Maximal levels according to Commission Regulation (EC) No 2023/915.

For the analyses on dioxins/furans/dl-PCBs/ndl-PCB the sample is extracted with organic solvents (hexane); the extracts are cleaned on an acid silica column/alumina/florisil/carbon. For recovery calculation all ¹³C labeled congeners are added. The concentrations are determined by GC-MS/MS.

Date report (dd-mm-yyyy):

30-07-2024

8861 CP
Harlingen
Nederland

Information about report

The results of examination refer exclusively to the checked samples.

All analysis results comply with EU requirements as indicated in Commission Regulation (EU) 2017/644 of 5 April 2017 laying down methods of sampling and analysis for the control of levels of dioxins, dioxin-like PCBs and non-dioxin-like PCBs in certain foodstuffs. Maximal levels according to Commission Regulation (EC) No 2023/915.

For the analyses on dioxins/furans/dl-PCBs/ndl-PCB the sample is extracted with organic solvents (hexane); the extracts are cleaned on an acid silica column/alumina/florisil/carbon. For recovery calculation all ¹³C labeled congeners are added. The concentrations are determined by GC-MS/MS.

Information about sample

BDS sample number 49520
Client identification 24TWS-EGG-TNB-01
Sample received on 30-07-2024
Start of test 02-07-2024
End of test 04-07-2024
Matrix Food, egg(product)
